After the Armistice (Nov. 1918) the Swiss army could gradually be almost wholly demobilized. The defence of the frontiers was entrusted to volunteer troops whose pay was fixed at from 8 to 10 francs (6 to 8 shillings) a day. This afforded a decent income at least to many who no longer earned anything, whether because of the direct effects of the war or of the prolonged military service in their own land. It was asserted that in consequence of the prolonged mobilization the Swiss soldiers had gained immensely in military efficiency. But it was a pity that such efficiency cost the little land of Switzerland between 40 to 50 million pounds, and this expense had to be met by raising the customs duties, taxes on excess profits, two sets of special "war taxes," etc., which, it was hoped, would bring in the necessary funds, if only after a lapse of many years.

Once again considerable bodies of troops had to be called up because of the general strike (Nov. 1918), which failed in a few days. And these extra troops were required also by reason of the break-up of the German and, especially, the Austrian armies, which flowed back like a flood, and threatened a regular invasion of Switzerland.

In Nov. 1918 Gen. Wille resigned his post, as he considered that his work was at an end. In the same month the military pensions were increased 10% and the export of arms and ammunition forbidden, while the bureau of the Swiss general staff was also dissolved.

To meet the emergency support of the families of poor soldiers during the four years of the mobilization period nearly £2,000,000 were expended. Both for the mobilized soldiers and for the volunteers the daily pay was raised to about 7s. Before the war ordinary soldiers received only 8d. a day. The old arrangements were put into force again in March 1920.

The defence of the northern frontier had to be strengthened again at the time of the signature of the Peace of Versailles (June 1919), for a huge immigration from Germany was feared. Later, the frontier police had also to be strengthened because of the great amount of smuggling and the enormous number of people who crossed the frontier because of the bad conditions of life in central Europe and the lack of employment, for Switzerland, as the sole non-enemy land open, was regarded as an El Dorado. On Aug. 28 1920 the watch on the frontiers was definitely abolished. The strict watch on the frontiers had greatly impeded all facilities for travelling, and the very severe regulations as to the visa of passports and payment of other dues were subsequently greatly lightened.

Economic Effects of the War—After the first excitement had died down, there were, in the first months of the first year of the war, no notable advances in the prices of various articles in Switzerland. This took place gradually, as the difficulties of importing articles increased. As early as Nov. 1914, Italy announced that she would place no hindrances in the way of the export of articles of food and supplies of raw materials.

In the matter of corn Switzerland was not in a very favourable position at the beginning of the war, for the supplies existing there would have barely sufficed for a couple of months. One must not forget that the Swiss agriculturists devote their attention far more to milk and cheese than to corn. This latter, therefore, could be delivered more cheaply by foreign countries, and was a far less profitable occupation for the Swiss farmer than milk and its products. Hence Switzerland fell more and more into a state of dependence on foreign countries.

The Swiss authorities naturally first of all attacked this pressing problem, and tried to find a remedy. They acted very shrewdly in that they introduced, Jan. 9 1915, a provisional monopoly of corn, and issued a special decree relating to its export. Thus the country was to a certain degree provided with the raw materials for bread and, above all, a bar was placed on all speculation in this most necessary article. Hence it was possible in the following month of May to note that the regular supply of corn was proceeding quietly, and that Switzerland was better supplied with corn than at the beginning of the war.

In the case of various articles such as bread and milk, a prohibition to export them was issued at once. It may cause surprise

at first to be told that milk was included in such a prohibition. But whoever is aware of the fact that nearly all the milk, so far as it is not consumed within Switzerland, was worked up into various shapes (e.g. cheese, butter, condensed milk) and then was exported in great quantities, will not find fault with this prohibition, when he learns that in Switzerland itself there were periodical milk famines for the native consumers. And it came to pass that milk itself was exported from Switzerland. For example, in the frontier city of Basle, the inhabitants at the beginning of the war were forced to exchange milk for vegetables grown in Alsace, because for ages the supply of fresh vegetables for Basle had been supplied by Alsace alone.

When the war had lasted about a year, and no end to it was visible, the necessities of life in Switzerland began to be not only more expensive, but also scarcer. In June 1915 it was therefore forbidden to export any articles of this kind. This regulation was due to the act of profiteers, who bought these necessities of life in huge quantities, and then accumulated them for export to central Europe. Switzerland now found itself in a rather awkward position. If she forbade the export of necessities of life, central Europe menaced the stoppage on their side of the import into Switzerland of the various articles which she most needed, such as coal, raw materials, artificial manure, etc. On the other hand, the Entente threatened Switzerland with a rationing of the consignments of necessities of life in case the export of such to Germany and Austria were not entirely stopped, for the Entente had soon discovered that for central Europe this matter was the sorest point in its war administration.

In the course of wearisome negotiations with both parties the Swiss tried to find a satisfactory arrangement. So first they tried to found with Germany some sort of organization for imports. Industrial firms founded private import trusts, e.g. in Geneva, under the name of *Société auxiliaire du Commerce et de l'Industrie*. A similar trust was created in St. Gall, and in Basle a so-called "Import Trust Company." It became harder and harder to assure sufficient supplies for the whole country. The imports of necessities of life from the "Free Zones" to Geneva were subject to strict supervision by France. On the heels of the corn monopoly of 1915 there followed in 1916 a monopoly of the importation of rice. In order to ascertain the amount of existing stocks of provisions within Switzerland the Swiss executive ordered a return of the supplies of such wares as were found in the entire country. As the supplies of necessities of life became scarcer, so did the prices rise steadily.

The "S.S.S." (i.e. *Société suisse de Surveillance économique*), with its headquarters in Berne, had itself entered on the commercial registry. Complaints were made by important members of the general public that by this action the exports and imports were placed practically under the control of the Entente. It was, however, too easily forgotten that naturally it was not the intention of the Entente to permit an uncontrolled import to Switzerland, and then an uncontrolled export to central Europe, and so supply its enemies with the things they lacked. But the Swiss rightly argued that it was absolutely essential for them to keep up a certain exchange of commodities with central Europe. For instance, cattle in great numbers were exported to Germany and Austria-Hungary, whence coals, iron, steel, manure, sugar and other needful articles were imported into Switzerland.

It would have been far easier to supply Switzerland with all these goods, had a larger number of railway goods trucks been available. But many were away in foreign parts in order to collect the accumulated goods in foreign harbours, because neither France, Germany, nor Italy had any trucks available for the through journey to Switzerland. Often the trucks were delayed for months on the way, or were utilized by the belligerents for their own needs, so that quite often Switzerland had to make protests, and to claim the return of its trucks. Even in 1921 France was still refusing to pay the sum agreed on for Swiss trucks held up and utilized by her. In consequence of this insufficient supply of goods trucks the import of corn to Switzerland was at one time quite blocked, and this caused no little anxiety in that country. As the feeding of the Germans began to be more and more diffi-

cult, and the prisoners and evacuated persons had to suffer thereby, many good persons in the Entente lands caused bread to be baked in Switzerland, and then, with other articles, to be sent to Germany for the use of the Entente subjects interned there. Switzerland had nothing to urge against this proceeding so long as there were sufficient supplies for its own people. But later on the supply of wheat for this purpose had to be specially delivered by the Entente. In the same year (1915) a prohibition to export cotton was issued, and from Nov. 25 onwards cheese could not be sent away in quantities of more than 1½ lb., and licences to export butter were no longer granted.

It was in 1916 that the profiteers were most numerous and most active in Switzerland. In April the Swiss executive had to make new and sharper laws against the speculators who chose the necessities of life as their field of operation. In Geneva a great organization was discovered which busied itself with such speculations. By order of the cantonal executive considerable supplies of coffee, cocoa, and chocolate were seized, and a number of foreigners expelled. Great quantities of rice and fat were also confiscated in Basle and in Buchs, on the Austrian frontier. One must assume, of course, that the greater portion of these goods had been smuggled over the frontier. Soldiers, customs officers, frontier guards had their hands full with countering the tricks of smugglers, speculators and profiteers.

Henceforward the economic relations began to get sharper and sharper. After the inquiry as to the existing stocks of sugar came the sugar monopoly. This had become necessary because the wholesale firms were no longer willing to undertake the importation of sugar. (Before the war Switzerland imported annually sugar to the value of about £1,500,000.)

As the blockade of the Central Powers by the Entente became more and more strict, this had a reflex action on the economical situation of Switzerland. That little country found itself hard pressed from all sides. In June 1916 Germany threatened the stoppage of all exchange of goods if Switzerland would not deliver those which had been stored on German account in Switzerland, and the Entente as firmly refused to let this threat be carried out. In the same month a Swiss delegation journeyed to Paris in order to remove these difficulties. But at first no settlement could be reached, for the Allies and Germany both obstinately clung to their points of view. Finally in Sept., with great trouble, an arrangement was concluded with Germany. Hardly was this in force when France, England, and Italy required that Switzerland apply to them measures similar to those which Switzerland had accepted in the Germano-Swiss arrangement. How complicated this situation often was for Switzerland is shown best by the Note, according to which the Entente required from Switzerland a prohibition for the export of all those manufactures (machines and parts of machines), the making of which required oil for greasing them which came from the Entente states. The distrust of Switzerland became greater and greater. Germany complained that Switzerland had abandoned its neutrality, and was under the protection of the Entente. On the other hand, the Allies grumbled that the goods delivered by them were handed over by Switzerland to the Central Powers. What wonder then that the saying became prevalent in Switzerland—"A neutral Power is kicked from the left, and whipped from the right."

The following fact will show how much during the war Switzerland had to depend on a reasonable amount of imports. In 1916, despite all the efforts of the Swiss farmers, only two-thirds of the supply needed for the country could be produced. Besides wheat for bread, raw materials, artificial manure, cattle for slaughter, fat, and by far the greater amount of the potatoes used, had to be imported from foreign parts (Germany, Holland and Italy). In 1916 Germany exported to Switzerland 1,600 trucks filled with potatoes, both for consumption and for sowing.

For foreigners it was not easy to understand why Switzerland placed the seizure of the harvest and the fixing of maximum prices for the most important necessities of life in the hands of the Military Department, for in Switzerland, as in other lands, so-called official Food Departments had been set up. It was easier to understand that the military authorities were empow-

ered to issue orders that the supplies of hay and straw of each harvest should be commandeered. Inquirers were informed that the Military Department or the Chief War Commissariat office had, in the course of years, accumulated a great stock of corn, which was renewed every three years. When, at the very beginning of the war (Aug. 27 1914) the Swiss executive sanctioned the grinding of "full flour" and then, as is well known, ordered a corn monopoly for the Confederation (Jan. 9 1915), and also commandeered the entire corn harvest, the Chief War Commissariat office was the right authority to carry these orders out. But on Aug. 1 1917 a central bureau for the provision of bread was set up, and on Aug. 10 1917 this was followed by a Swiss bread bureau. On Sept. 13 1918 a Swiss Provision Department was resolved on, and the bread matter was entrusted to it.

The entry of Italy into the war (May 23 1915) was a hard blow to Switzerland, making it more anxious than ever, but still worse was the declaration made by Germany (Feb. 1917) to the Allies of the unrestricted submarine warfare. By this step Germany won no sympathy from the neutrals, although the Swiss executive refused the suggestion of the United States to break off all diplomatic relations with Germany. The Swiss held that this refusal was in accordance with their neutrality, as Germany was the sole land which supplied coal to Switzerland, for the Entente had now to send coal to Italy and could not supply it to Switzerland. At any rate Switzerland got coal from Germany, despite increased prices, cheaper than Italy did from its Allies.

The declaration of Germany (on Feb. 1 1917) that the port of Cetté lay outside the blockade zone was only a poor comfort for Switzerland. It ought to have secured previously a reasonable amount of imports. France strained its resources to satisfy the demands of Switzerland as far as it could, and sanctioned important traffic alleviations for the transport of necessities of life. But this did not hinder the needs of Switzerland from being increased. On Feb. 12 1917 two "meatless" days per week were ordered, and on other days only a single dish of meat was allowed for each meal.

One misfortune followed another. Soon the Argentine Republic announced (April 1917) that it had forbidden the export of wheat,—even the supplies already bought by Switzerland.

However, it must not be thought that during this critical period Switzerland had simply folded its hands on its breast. It tried as far as possible to make itself independent of foreign countries by directing additional planting of potatoes, vegetables and materials for bread. Flowers disappeared from all gardens. Everywhere their place was taken by potatoes and other vegetables. The pleasure parks and drill grounds in and around the towns were commandeered for the same purposes. In the evenings, when the day's work was done, the workmen of the towns were seen, pick and hoe in hand, busy turning up the ground which previously had served all purposes except the planting of useful things. The State ordered each parish to put gratis at the disposal of the poorer classes land for cultivation, and even swampy spots had in all haste to be prepared for cultivation. It is easy to understand that sometimes practical impossibilities were demanded. "One lives and learns." Next, after the land had been prepared for cultivation, suitable kinds of manure were no longer to be had. Those who were not owners of cattle could produce none. Artificial manure of good quality proved too dear to be purchased by poorer people. These were obstacles that must not be underestimated, but absolute need and the horrible period of the war overcame them all. Frequently the results of this compulsory planting did not even approximately reward the pains and work which had been bestowed upon it, but people were too filled with joy to despise the little that was actually the result. Thousands and thousands of families who previously did not produce necessities of life had themselves to plant the amount of potatoes and vegetables required for their own use, and so considerably relieved the crying need. In 1917 120,000 trucks of potatoes were produced (the normal production was about 100,000 trucks). But there was no abundance of this commodity, for in many poorer families potatoes had to replace macaroni, and such like wares which had become more expensive.

These measures on the part of the Swiss authorities were indeed very drastic, but they could not have acted otherwise. The townsman, like the country farmer, was affected by them. The latter indeed had to submit to regulations which meant a revolution in his ordinary business. He was ordered, without the slightest regard to the number of his cattle, to plant a fixed quantity of his land in corn, in such and such a manner. With far less help than heretofore (for the men of military age were generally absent), the peasant women and their half-grown children had alone to do all the work. Not infrequently even their horses were taken away for service on the frontier.

When the peasants had planted, as ordered, the fixed quantity of land in corn, and so helped in the supply of bread, it turned out that now they had too little hay for their cattle. Experience taught here, as elsewhere, that an existing state of things could not be simply changed by the alteration of a screw in a machine. The aforesaid regulations reminded men of the State right of tutelage in the matter of dealings with corn, as had been usual in Switzerland as late as the 18th century. Great quantities of corn were procured and stored in granaries, in order to secure cheaper bread to the people in general.

The more profitable pasture business (e.g. breeding of cattle and milk industry) had developed from agriculture. Before the war there were big farmers in Switzerland, who only grew potatoes and other vegetables enough for their own use. But the rest of the land was laid down in grass. So it is easy to understand that before the war Switzerland could export yearly huge amounts of cheese, butter, and condensed milk.

Against the introduction of "bread cards" Switzerland fought with tooth and nail. The workmen in the towns were not willing to be deprived of their unrestricted amount of bread. A middle way was therefore tried in Switzerland—the grinding of the corn less finely, and the prohibition of the sale of fresh baked bread (Feb. 12 1917). Further, in May, a decree directed that bread should only be sold 36 hours after it was baked. But already in Oct. the final solution of this problem could no longer be deferred—the daily ration of 9 oz. a head.

Bread and meal were joined on the same card. The bread card was split up into such small rations that the traveller could obtain in the hotels and restaurants per portion only 1½ ounces. This regulation was followed in Feb. 1917 by the order to make macaroni, etc., only out of eggs, and then on March 1 1917 appeared the cards for rice and sugar. In the case of sugar about 2½ lb. extra were allowed per head for making jam.

Every month or two Switzerland had to start new negotiations with the belligerents, and to conclude new agreements. In May 1917, the negotiations about the management of the S.S.S. were brought to a conclusion, and an understanding was reached about the import of fodder and the export of live cattle. For the export of fodder from the Entente lands, Switzerland had had to export live cattle as "compensation." A new economic agreement between Germany and Switzerland was also concluded.

A special chapter in the provisioning of Switzerland was formed by the struggle about the price of milk. Here the consumers and the producers were often hotly opposed to each other. The workmen in the towns reproached the peasants with illegal exploitation of the hard lot of the people, and that the latter often from time to time intentionally brought about a milk famine in order to drive prices still higher up. The "Town Associations" (a product of the war as against the country) took an active part, though not always with the same arguments, in this struggle against the peasants. These, on their side, refused absolutely, seeing that all kinds of fodder were always becoming dearer, and by reason of the general rise in prices, to supply their wares at the same fixed price. It was not always easy for the authorities in case of these quarrels to hit on a middle way which was good for all parties alike. One reason for the scarcity of milk was certainly that Switzerland temporarily exported many head of cattle, and this business wasted much milk. Then again, as butter and cheese rose in price, greater supplies of these articles were manufactured, as it was the more profitable business. All this took place, be it well understood, at the expense of the consumer, who had to suffer much thereby.

In order to assure nevertheless a sufficient supply of milk for the Swiss people in general, the Swiss executive empowered the Agricultural Department to fix the amount of the milk rations allowed to each parish, and sanctioned the delivery of milk at

reduced prices to persons of small means. The maximum price for a litre (1½ pt.) of milk was therefore fixed at 33 centimes (about 3½d.) in April 1917, but for people without means at 26 centimes (about 2½d.). The State and the parishes had between them to make up the deficiency. In order to create a closer organization and to render the commerce in milk somewhat the same for all 22 cantons, a central bureau for the supply of milk and its products in Switzerland was set up in Aug. 1917. It was empowered to issue decrees, and to subject the whole industry to Federal control. That was quite necessary, because it happened that the milk for the inhabitants of the towns was already rationed (so in Berne on Jan. 1 1918 the daily allowance a head was only three-fifths of a litre), while in the country free trade prevailed in this business. As the danger of a fresh rise in the price of milk became more and more imminent, the town workmen opposed it vigorously. They threatened a general strike if this most essential commodity should be again raised in price. In the Chamber of Deputies of the Swiss Parliament a compromise was made on this basis—the Swiss executive to grant one rappen (less than a farthing) per litre to the milk producers, and to pay the extra expenses of the transport—this was only to avoid a fresh rise in the price of milk (Oct. 1917). This was well meant, but it turned out later to have been a mistake, since from this time onwards rich and poor profited by this arrangement, and the Swiss authorities had to pay out a huge amount of money.

For the time certain kinds of cheese (cream cheeses, etc.) were not allowed to be sold, and the consumption of butter was restricted. Finally, it was arranged that each landowner was obliged to deliver a fixed quantity of milk from each cow for consumption. When later in 1918–9 the rationing was still more limited (Oct. 1, half a litre, and in Nov. one-third litre per head) this evil was not so much due to any intentional over-production of milk products by the peasants, but, as pointed out above, because many peasants by reason of the compulsory planting of corn, and dearer hay, etc., and the consequent hay famine, could afford only to keep a far smaller number of cattle. This circumstance may have affected the production of milk more than was stated above. It must be added that children up to a fixed age and persons over 60 could claim an extra ration—so too sick persons, but for these a medical certificate was necessary.

At the beginning of the war people were much perturbed by the payment of 26 rappen (about ⅓ of a franc) for a litre of milk, and yet in 1921 the price was 52 rappen (about ½ franc), or an increase of 100 per cent. After the conclusion of peace and on the return of more normal economic conditions it was hoped that a slight alleviation would ensue. But in 1919–20 the foot-and-mouth disease in Switzerland increased to such a degree that at the end of 1919 the daily ration of milk in the towns sank to below the average in the war-time—to one-third of a litre. The foot-and-mouth disease caused Switzerland a loss of about £5,500,000. Finally, in April 1920 this limitation was abolished. The milk famine was one of the greatest calamities that occurred in Switzerland during the entire war period.

It goes without saying that macaroni, groats and oatmeal, barley, cheese, butter, fat, and oils were all rationed, and even also, in part, potatoes and coals. The supervision took place by means of specially issued cards. The butt of the card had to be given up every month when new cards had to be procured. These bore every month differently coloured signs of authenticity. A regulation was also made that in each household even necessities of life, which were not rationed, should not be kept in quantities exceeding the supply required for two weeks.

Some necessities of life were meted out with a very sparing hand: thus only rather over 1 lb. of meal per head and per month was sanctioned, while, from Oct. 1917, white meal and groats were only allowed for hospitals and sick persons, and, even to procure these, corresponding bits of the bread and meal card had to be sacrificed. Other important necessities of life were rationed as follows: maize about 14 oz., rice about 9 oz., and sugar about 20 oz.—in each case per head and per month. But even these rations were not fixed fast—on the contrary they were raised or lowered according to the existing supplies imported.

The restrictions that were most felt were those on butter and on fat for cooking. Foreign lard, even before the outbreak of the war, had been imported in great quantities. But afterwards the imports of this article fell off more and more—in July 1917 it had decreased by 90 per cent. Hence the supervision of all kinds of fat was placed under State control, and in Jan. 1918 a so-called "Central Bureau for Fat" was set up to ensure the provisioning of the country with fat and oil, both for eating. The fat and butter cards (fat for eating and oils) were brought in on March 1 1918. They allowed about 12 oz. of fat and about 5 oz. of butter per person each month. In June the ration of butter fell to about 3½ oz., and then rose again to about 9 oz. After the Swiss Government succeeded in buying in America (Jan. 1919) 15,000 tons of pigs' fat, it became possible to abolish the rationing of fat in July of the same year, but the butter cards remained in use for two months longer.

About the same time (July 1919) the rationing of macaroni, groats, oatmeal, and barley was abolished, and two months later (Sept.) the same was done with the bread and meal cards, and finally with the "meatless" days.

For the poorer classes so-called "Distress Relief" was organized, i.e. the Confederation, the cantons, and the parishes together paid over to these poorer people a portion of the price of certain necessities of life. The principal objects of this charity were bread, milk, and potatoes. In the towns many classes of the population had to be supported in this manner—in the town of Berne alone about 27%. In the summer of 1918 the increase in the prices of necessities of life rose to 120%, and in the autumn of the same year to 150%. Throughout the country the town workmen organized demonstrations against this increasing cost of necessities, and these were combined with other matters of political discontent, these latter being stimulated by the events in Russia and in Germany and all leading up in Nov. to the general strike (see below).

Manufacturers in general accommodated themselves quickly to the state of things produced by the war. An exception was formed by the embroidery industry of eastern Switzerland, which was paralyzed through insufficient exportation and lack of foreign orders. On the other hand, the watch factories did very well, because they could manufacture parts of ammunition for the belligerents, which brought in much money, both to masters and men. The same thing happened with the great industrial magnates, who manufactured turning lathes, machines or parts of machines for the same object, and exported them. The delivery of completely manufactured ammunition was forbidden by the Swiss executive as being contrary to neutrality, but it was not difficult to get round this prohibition. Each of the belligerents sought to arrange matters to its advantage. Germany once claimed that every manufacturer of western Switzerland who delivered articles to the Entente should receive no more German coal for his factories. France, on the other hand, forbade the use of grease for machines and parts of machines which were to be exported to Germany. It was not always easy for Switzerland to steer the right course, without totally depriving its workmen of their wages.

The provisioning of Switzerland with coal proved often a very difficult and complicated matter. At the beginning of the war, and in part even up to the year 1916, it was not possible to complain in Switzerland of a coal famine, properly speaking, for the prices had risen by not quite a quarter per ton. Before the war one had to pay to the coal merchant (including his profits) about £2 8s. per ton, and in 1916 some 7s. or 8s. more. But matters changed altogether in 1917, for not only did the price (including the profits of the coal merchant) rise to £5.4s. but restrictive measures were taken. By a decree of the Swiss executive of March 7 1917, no one was allowed to procure a supply of provisions sufficient for over three months. In basic the so-called "Central Bureau for Coal" was set up. Any person who required more than five tons of German coal had to take a share in the aforesaid company, or else to pay an extra £2 per ton. The object was to secure to Germany an adequate money advance, probably in order to compensate her for the loss on the exchange. Germany was required to provide solvent guarantors, so as to make sure that the money would be forthcoming. Later on, a local "Coal Supply Bureau" was set up in every town and every parish, which fixed the amount that any person could be allowed, and supervised the distribution. The prices for good coal (including merchants' profits) amounted to £10 per ton. New restrictions were often issued. The census of the amount of coal was soon followed by its rationing. It is well known that Switzerland, apart from peat and some slate coal, possesses no coal proper. That fact suffices to prove how dependent she is in this respect on foreign supplies. A "Swiss Coal Co." was formed, the object of which was to support financially efforts to find more coal in the country. Researches were carried on all over the land, and a certain amount of coal of poorish quality was found in the cantons of Berne and of the Valais. Peat too was cut, wherever there was a possibility of the smallest supply. But one cannot be surprised that, despite the high prices, the quantity of this coal fell far short of the amount required.

Soon after the scarcity of coal began, and particularly by reason of the rise in its price, the railways and the steamboats on the Swiss lakes were forced not only to raise their fares, but to take other restrictive measures. First of all the "excursion tickets" were suppressed, and then also the cheaper sorts of return tickets abolished (1917). The circulation of trains was reduced from March 1918 by a third. In Nov. 1918 the State railways raised their tariff for goods by about 80%, and in the same month experiments were made with supplying locomotives with wood instead of coal, and thus, in consequence of the ever-increasing coal famine, even in the case of fast trains. The cantons were each bound to deliver a certain quantity of wood, according to their size and their supplies. Canton Berne, in particular, had to furnish very large quantities of beech wood. Previously, the whole supply of fuel had been seized by the State. All public bureaux and post-offices had to reduce the hours during which they were open, schools had to have holidays, etc. One restricted railway scheme appeared after another, and from Dec. 1 the circulation of travellers, on those bits of the railways which were still run by steam, was provisionally entirely suspended on Sundays and festivals. The only trains allowed on those days were those which carried milk. At the same time the distribution of letters on Sundays was discontinued.

In this time of need strenuous attempts were made by the Swiss authorities to electrify the railway lines, where this could be done

most efficaciously. The private non-State railways were encouraged to do the same, and subsidies were promised to them for that purpose. Although, with certain exceptions, such as the St. Gotthard line and some smaller bits, this permission could not be utilized to the extent required, this is to be explained by the unheard-of prices asked for raw materials. The purchase of electrical machines alone absorbed such huge sums that the necessary capital could not be brought together.

In Oct. 1920 a fall in the price of coal took place, and the supply also gradually became better than heretofore, so that in the winter of 1920-1 the rationing of coal was abolished. The coal supply organization in Basle was wound up. But now another difficulty appeared. In consequence of the augmented supply the "Central Bureau for Coal" had acquired great quantities of coal at prices which were still high. Likewise the supply of peat had increased in amount. But as the coal prices sank the supply could not keep pace with the reduction in prices unless at a great loss. Business men complained that they could get coal direct from the pits at lower prices than those payable in Switzerland. The Swiss executive resolved to give financial aid for the distribution of the existing stocks in the country at cheaper prices. But it imposed on each ton of imported coal an extra customs duty, and this measure was to last until this advance was reimbursed.

Treaties—In order to complete the picture of the economic difficulties which existed in Switzerland during the war we must here add a short account of the treaties which she was compelled to conclude with the belligerents.

The "S. S. S." (*Société suisse de Surveillance économique*), intended to regulate the circulation and employment of wares in the interest of the Entente, was founded on Oct. 11 1915. At the same time the "Treuhandsstelle" for commerce with the Central Powers came into existence.

On Sept. 2 1916 the so-called Economic Agreement was concluded to facilitate the exchange of goods. Germany by this had to release per month 253,000 tons of coal, and the amount of iron and steel required by Switzerland. Switzerland, on the other hand, handed over products of milk, meat, etc. A Swiss export committee looked after the export of war supplies, produced with German raw materials (the so-called "Swiss Central Iron Bureau"). It was forbidden to use German iron or German coal for the production of war supplies destined for the Entente.

On Aug. 20 1917 a new arrangement was made. Germany was to grant permission to export 200,000 tons of coal at £3 12s a ton, and 19,000 tons of iron and steel, in both cases per month. On its side, Switzerland was to grant Germany a credit per month of £800,000 (foundation of the "Central Bureau for Coal").

On Sept. 29 1917 this arrangement was followed at once by a similar agreement with France. A group of Swiss banks granted to a group of French banks a credit per month of £500,000, this to last from October to December. In return Switzerland obtained from France certain economic reliefs. After two months this arrangement was renewed for 10 months, the credits allowed rising with certain improvements in the import of goods. On March 20 1918 a similar credit was granted to a group of English banks, the monthly maximum amount being fixed at £400,000.

On Aug. 30 1917 an agreement with France and Italy was concluded for the export of wood, to be worked up, from Switzerland. On Dec. 5 1917 the United States also made an agreement to supply 240,000 tons of bread-stuffs, till the next harvest. Other kinds of goods were "contingented." The lack of room on ships delayed, however, the delivery of these supplies very much. In place of the agreement with Germany (which had run out) a new treaty, much less favourable, was concluded (May 15 1918). Germany was bound to give leave for the export of 200,000 tons of coal, iron, and steel. The Swiss "Treuhandsstelle" had to superintend the exchange of goods according to the S. S. S. system.

The Economic Agreement of May 5 1915 with Italy was still in existence. But on Nov. 1 1918 an economic and financial treaty was made with this country, as also with France and England. The credit to be allowed every month was fixed at a maximum of £200,000, but the amount of imports was limited.

In order to execute all these financial obligations of Switzerland the "Swiss Financial Association" was founded in Lucerne on Aug. 1 1918. To protect itself against the imminent danger of a maritime blockade, Switzerland agreed with Germany on April 24 1918 that free passage should be given for all cargoes destined for Switzerland.

In a fresh financial agreement with France (July 19 1919) Switzerland obtained a credit of about £1,250,000. The economic treaty with this country ran from March 25 1919 to the end of 1919. In Oct. and Nov. of that year the contingents of Switzerland for watches and embroideries were somewhat raised. In a fresh agreement of March 10 1920 a bargain was made with Switzerland for the delivery of 10,000 tons of coal (brown coal) from the pits on the left bank of the Rhine each month. Switzerland had to supply, among other things, electric power, but the promised amount of manure received by Switzerland was quite insufficient.

At the end of Nov. 1919 a new compensation treaty was made with Italy about the delivery of oil-cake and hay in exchange for cattle, for breeding and use.

The coal agreements came to an end in the beginning of 1919.

On Jan. 22 1919 an economic treaty was made with the United States, bigger contingents of goods were secured to Switzerland and a tonnage of 70,000 (soon raised to 100,000), England and France guaranteeing these amounts.

On March 25 1919 yet a new agreement was made with France about the supply of goods. France promised to deliver 60,000 tons of coal from Lorraine per month (at £4 16s a ton) and also manure and facilities for the transport of goods. On its side Switzerland engaged to deliver cattle for breeding and certain goods (chocolate, watches, embroideries, etc.) to the value of about £108,000 per month, and also a new credit not to exceed about £1,500,000 at the most.

The credit arrangement with England of March 20 1919 was not renewed. Later on, England too raised the contingents which could be imported, and sanctioned (March 1 1919) again the admittance of embroideries and silken goods. On April 28 1919 the "black lists" were abolished, and also the certificates of nationality and the contingents of imports permitted by the S. S. S.

Such were the economic agreements which Switzerland had to sign. Her economic dependence on foreign countries is thus abundantly clear, and yet it must be said that all the belligerents had taken much kindly notice of her position in this way or in another. It must be recognized that the Swiss authorities managed to get well through all their difficulties, and did not fail to take precautionary measures (sometimes very incisive) to provide the Swiss with all the necessities of life. But, in consequence of the incredible rise in prices and the excessive prices of necessities of life, even of those which are most indispensable, they were unable to bring it about that the distress of the people should not lead to dissatisfaction, complaints, and great discontent.

General Strike of Nov. 12 1918—The Swiss Socialists (or Social Democratic party) were never stronger, and to a certain degree more feared, than towards the end of the fourth year of the war. The rise in prices of all commodities, and too the unforeseen and the previously unknown dearth of dwelling houses, were utilized very cleverly and ably for the purposes of propaganda, and brought great reinforcements to the Socialists. Protest meetings against too high prices were organized, and these were sometimes accompanied by political demands which caused serious restlessness. The revolution that had broken out in Russia in the preceding year and the break-up (Oct. 1918) of Germany, from the military point of view, and in part also from the political point of view, hurled their waves of revolt as far as Switzerland. Here the leaders of the workmen imagined that the moment was come for violent action. The crisis was the summoning of troops to Zürich, the Government of which on occasion of the memorial day (organized by the Socialists) of the Russian Revolution, feared serious riots. The calling of the troops to Zürich was considered by the workmen as a provocation, and the reply was a general strike for 24 hours, which very soon developed into an unrestricted general strike in the whole of Switzerland. The railways ceased to run, and in most Swiss towns the entire body of workmen took a holiday, though not in the rural districts or in western Switzerland where the strike was sometimes only a partial cessation of work, and ended in a speedy breakdown. In order to make this general strike more popular with the workmen the so-called "Olten Committee of Action" put forth a social and political programme, which was submitted for speedy acceptance to the authorities, and included the following demands. The immediate transformation of the Government of the country so as to be in accordance with the will of the people. The new Government was to bind itself to the following programme at the very least, new election of the "Conseil National" according to the principles of proportional representation; voting rights of all kinds for women; introduction of the general obligation to work, and of the 48-hour week in all public offices and private businesses; the reorganization of the army so as to make it the army of the people, the securing of the supplies of necessities of life, this provision to be carried out with the agreement of the rural producers; insurance for old and sick persons, State monopoly of imports and exports; and redemption of all State debts by the rich.

The Swiss executive refused to negotiate with the strikers, and the peasants made a show of cutting off the milk supplies of the towns. Another hope too of the strike leaders failed. They had expected that the soldiers, especially the members of the association of the "League of Soldiers" (thought to be imbued with revolutionary ideas and later forbidden by Gen. Wille), would

naturally refuse military obedience. The military authorities, however, had taken the precaution to summon trusty troops from the rural and Alpine regions, and so the leaders of the strike saw their hopes falsified. When the news spread of the ultimatum issued by the Swiss executive to end the strike at once, otherwise the strike leaders would run the risk of being put into prison, the general strike came to a natural end. Such a strike has seldom broken down more wretchedly. The 48 signers of the "Olten Appeal" were accused of instigating the strikers to mutiny, and so were handed over to the military authorities for examination. By this accusation was meant any appeal which directly or indirectly was made to the soldiers, with the warning not to march against their own brothers, and not to turn their weapons against the workmen, but, in case such a command should be given, rather to refuse military obedience. By far the greater number of the 48 signers were acquitted. Only a few of the most prominent and the most compromised leaders were kept, and received punishments ranging up to six months' imprisonment. Here, as elsewhere, it became clear that the greater part of the Swiss workmen never would approve a united general strike with purely political aims.

Interned Prisoners—As early as Oct. 1914, a beginning was made with the dispatch of the evacuated civilians home to France, Germany, and Austria, passing through Switzerland. And up to March 5 1916 some 60,000 persons were conveyed back to France alone by the same route.

On Feb. 21 1916 an arrangement was finally made about the exchange of the severely wounded German and French prisoners who were to pass through Switzerland. After the consent of the Swiss Red Cross had been previously obtained, this duty was confided to it by a decree of the Swiss executive. Now began the foreign action of that institute which lasted for five long years. Constance and Lyons were fixed on as the exchange centres, the trains were to pass through Switzerland at night, and the railway carriages required were to be furnished by the State railways.

Before the actual transport took place, "selection committees" visited the various prisoners' camps, in order to inspect the severely wounded men, and to settle which should be included in the exchange. The Swiss Red Cross agreed to defray all the expenses for the food, etc., of these poor men, and their nurses etc., but not the railway fares.

Besides the medical men, male Red Cross nurses accompanied the trains, sometimes also soldier nurses, while women nurses from nearly every Swiss nursing home looked after the invalids. The journeys took place at longer or shorter intervals, but often there were lengthy breaks, due to the state of the war, and to difficulties that arose between the hostile states.

The Swiss people took a great and a very sympathetic share in these transport trains. People flocked from long distances to the railway stations merely to see the trains rush past, and had the feeling that thereby they had showed their sympathy with the unfortunate victims of the war. At the places where the trains halted, the joy was enormous. At some spots the trains had to stop because the people would block them by standing on the rails, and a huge quantity of loving gifts, for which room was scarcely found, literally overflowed the Red Cross carriages.

The good example of France, Belgium, and Germany was followed in Nov. 1916 by Italy and Austria also. The exchange stations here were Como-Monza and Feldkirch-Dornbirn, and many trains came through with Austrians, Bulgarians, Turks, Serbs, English, and Italians. Later on, when Austria resolved to repatriate the numerous Italian consumptives, whose illness was still in the preliminary stages, special consumptive trains became also necessary. Imbecile soldiers were transported in great numbers. Twice trains, with many such, came through, and no one could determine their names or their homes.

A most pitiful and moving spectacle was the sight of the trains filled with evacuated civilian travellers. Old men with snow-white hair, women of all ages, and children, even unweaned infants, were seen in these trains. These unfortunate persons were warmly welcomed and well fed, in the most hospitable fashion. It is a gloomy chapter in the history of the war.

The interned soldiers were mostly housed in the Alpine regions. This took place for various reasons. First of all, the high air was looked upon as a great factor in their convalescence, and then again they were isolated from the temptations of bigger places and towns, and, finally, in the tourist centres many hotels stood empty, all ready to receive this new kind of guest, and well fitted to shelter great bodies of interned.

No Swiss industry was so hard hit by the war in its very existence as the Swiss tourist traffic, once so flourishing. According to the statisticians, milliards of francs were invested therein, and so, soon after the outbreak of the war, special measures of protection (such as exemption from bankruptcy suits) and also acts of charity had to be taken. What wonder then that the Swiss authorities, by this action in favour of the interned, hoped to kill two birds with one stone, and appropriate these small profits to the stricken *industrie des étrangers*?

The daily sum paid for accommodation, etc., per head was originally four francs, later five francs, and even in 1921 an extra amount of one franc daily per head for 1918 was the subject of negotiation. (These sums were paid by the respective states concerned.) But no state, save defeated Germany, had agreed up to June 1921 to this extra expense. The food was simple and nourishing, and in some places it was more than good.

At the beginning of the period of internment the interned were given free postage for all letters sent to their native countries. And nothing too was charged for parcels sent thence to foreign countries. This humane arrangement was afterwards first restricted, and later on quite suppressed, as the war seemed to be never ending, and the cost to the Swiss post-office ran up to £2,000,000, and even more.

A great difficulty arose as to the employment of the interned. In some places they took to an industry which promised them certain profits. Such were the beautiful, and even most artistic works of art which were produced by simple and untrained soldiers. They acted as joiners, mechanics, turners, wove baskets, made ropes, and nets, painted pictures, etc. In Thun, as early as 1916, a school of commerce was opened for the interned. The universities of Basle, Berne, Geneva, Lausanne, and Zurich allowed interned to matriculate as students. The Bernese University Committee provided in 42 prisoners' camps outside Switzerland both teachers and students with money, food of various kinds, clothing and books. The interned were permitted to hold exhibitions of their products, and special committees were founded to promote the sale of the fruits of their labour. Now and then they received visits from high-placed countrymen (such as Gen. Pau, etc.). They looked after their social amusements themselves. One English committee even got together money for the visits of English women to their husbands interned in Switzerland. The English interned enjoyed the special sympathy of the Swiss. The number of prisoners interned in Switzerland was already in Aug. 1916, 18,936—11,823 French, 4,322 Germans, 1,607 Belgians, 1,183 English, and one Austrian. These numbers later increased very much, and finally, when difficulties arose about food in Switzerland, it could not possibly receive an unrestricted number, and so after a certain time the interned were exchanged for others.

When the internment of wounded prisoners was resolved on in Switzerland this business was entrusted to the chief army medical officer, and the Swiss Red Cross. Practically, the Red Cross took charge only of the transport of the interned to and from Switzerland, everything else being supplied by the army authorities. The interned had fewer invalids than the exchanged prisoners, and so required only ordinary trains with occasional carriages in which to lie down, but many persons seriously ill were sent home, and the Swiss Red Cross looked after all such cases.

After the Armistice the principal transport of the prisoners belonging to the Entente took its start. The sick and invalids were partly sent for in special "sanitary" trains,—French, English, American, and Italian,—the nurses, etc., being supplied by the Swiss Red Cross. All these journeys passed off without any serious accidents, at least it never happened that any one was injured, though the trains went at express speed.

The Swiss Red Cross spent (apart from the railway fares) some £13,000 in carrying out this transport. No fewer than 81,377 persons were conveyed by the Swiss Red Cross, and that without counting the numerous civilians interned and civilians evacuated, who had previously passed through Switzerland, the number of these amounting to several hundred thousands. All these persons travelled through Switzerland.

In April 1919 there were still 5,000 Germans interned in Switzerland. These could only be sent home later, shortly before the home-coming of the prisoners interned in France.

The international action of the Swiss Red Cross extended also to investigations as to prisoners and missing soldiers. From all parts enquiries arrived, relating to the whereabouts of various soldiers. This was a task which properly belonged to the International Committee at Geneva, specially created for this purpose. In many cases, however, the Swiss Red Cross, thanks to its fortunate and useful communications by reason of the exchange of the interned, could answer these enquiries. With this object a special office was set up in Berne for the interned prisoners of war in Switzerland, and to this all enquiries were to be addressed, whether for interned persons or missing persons.

International Red Cross at Geneva—The following was the share of this well-known institution. When hatred and reprisals on both sides got the upper hand, it issued a series of appeals, first of all in favour of common action in carrying out the task of the Red Cross, next to the belligerents on behalf of the wounded and sick, of the nursing staff, of their supplying necessary wants in accordance with the Convention of Geneva, and of the Hague Convention. Next came protests against the torpedoing of hospital ships and against the bombardment of hospitals on the field, the protection of Red Cross unions, the recognition of the Red Crescent, as to the treatment of prisoners, and the distribution of money collected (about £13,000) to the Red Cross associations of the belligerents, as to the reception of Red Cross workers in Switzerland for rest and refreshment, missions to visit camps of sick prisoners in Italy, Bulgaria, etc., and prisoners' camps in general, the facilitating of communications between the Red Cross associations of the several belligerents, in favour of the sending home certain categories of war prisoners, against the propaganda bureaux, and against the employment of poisonous gas, etc. That is only an imperfect list of the tasks which the International Red Cross undertook, and which it would take a book to describe in detail. Its influence was not less blessed than that of the Swiss Red Cross, and was of extreme importance for facilitating communications between the belligerents. It is worth mentioning that the French poet, Romain Rolland, gave half the proceeds of his Nobel prize to Gustave Ador, the president of the International Red Cross in Geneva, for the war prisoners.

Help Given to Other Nations—As early as June 28 1915, Switzerland hearkened to the cry of distress from little Luxemburg, then occupied by the German, and sent flour to help its suffering population. On Oct. 6 of the same year the Luxemburg Minister of State, von Eyschen, came to Berne to arrange for the supply of the necessities of life to his country through the Swiss "Import Trust." The principality of Liechtenstein was supplied also with food-stuffs, this led to its closer association with Switzerland, and in 1921 it had Swiss postage stamps and used francs as money. On Dec. 4 1918, shortly after the Armistice, Switzerland, in order to alleviate the hunger in the German districts of Austria, sent ten trucks, laden with flour, and nine with rice, to Innsbruck. These supplies were reimbursed by the Entente, as also were the 100 trucks of necessities of life sent on the 27th of the same month. Switzerland was selected as being able to send supplies quickly. Later, she sent them from the stocks meant for her own consumption.

But this kind of help was not the only sign of sympathy shown by Switzerland. When the need increased it extended its charity to the reception of badly nourished children belonging to the belligerent states. In Sept. 1916, 760 Belgian children from the occupied territory were long in the canton of Fribourg. In other Swiss cantons such poor children were also received. In the year 1919 alone a total of 43,000 foreign children was received in order

to recover from illness. It were principally Belgian, Austrian, and German children who benefited by this act of charity.

Obituary, 1910-21.—Death was especially busy with the great Swiss historians during the decade 1910-20. J. Dierauer (1842-1920); W. Oechsl (1831-1919), Karl Dändliker (1849-1910); B. van Muyden (1852-1912) passed away, as well as Jakob Heerli (1853-1912), the principal authority on prehistoric Switzerland, Adolf Wäber (1841-1913), the bibliographer of works of travel in Switzerland; Caspar Decurtins (1855-1916), the great authority on the Romansch dialect; Jean Grellet (1852-1918), the well-known writer on Swiss heraldry, Emilio Motta (1857-1920), the founder and also the editor (for 35 years) of the *Bollettino della Svizzera Italiana*, which rendered such great service for the history of Italian-speaking Switzerland, and Henri Fazy (1842-1920).

The fine arts also mourned the loss of Ferdinand Hodler (1853-1918), the merits of whose pictures were so hotly discussed during his lifetime, Max Buri (1868-1915), the delineator of Bernese peasant life, and Eugène Burnand (1850-1921). To these losses we must add Richard Kissling (1848-1919), the famous sculptor; and J. R. Rahn (1841-1912), the historian of Swiss art.

Other Swiss, each eminent in his own way were Theodor Kocher (1841-1917), the world-famous surgeon; F. Imhoof-Blumer (1838-1920), the celebrated numismatist; F. A. Forci (1841-1912), the physicist and monographer of the Lake of Geneva; Johannes Conz (1822-1918), the great authority on Swiss forestry, and a mountain climber whose active career ended in 1850; J. H. Graf (1852-1918), the mathematician and leading authority on old Swiss cartography; and, last but not least, J. H. Dunant (1828-1910), the founder of the International Society of the Red Cross at Geneva.

We must not omit a group of men of letters of the "Suisse Romande"—Gaspard Vallette (1865-1911) and Philippe Monnier (1864-1911), and the novelist Edouard Rod (1859-1910).

Our list may be brought to a close with the names of the linguist, Ferdinand de Saussure (1857-1913), and of the Romance scholar, Heinrich Morf (1854-1921).

Miscellaneous—Perhaps the most important event which happened in Switzerland in 1920 was the first meeting of the League of Nations in Geneva, a spot selected, it is said, by President Wilson. In Feb. 1921 Switzerland declined to allow the passage of police troops to guard the peace in the Vilna popular vote.

Switzerland has adopted officially the day of 24 hours, running from midnight to midnight.

Naturally, the possibility of winter sports in Switzerland was excluded (save for the natives) during the war, and they had not quite reached their former vogue even by 1921.

The long war had a most disastrous effect on the Swiss hotel industry. Previously to it far too many big hotels had been built, so that the whole industry was overcapitalized and in a state of great indebtedness to the banks. After the end of the war many hotels were pulled down or diverted to other uses, even in such frequented spots as Interlaken and Grindelwald. It has been stated by H. Gurtner that the total capital invested in the Swiss hotel business was in 1912 about £45,500,000, or about one-thirtieth of the total amount of the wealth of Switzerland. The same writer puts the total value of the hotels in the Bernese Oberland at about £6,000,000 just before the outbreak of the war.

On May 15 1914 a great national exhibition was opened at Berne. But the speedy outbreak of the war nearly ruined it.

The rate of exchange on London varied much during the war. After the first shock it rose to over 26 francs (par 25), but then sank, and attained its lowest point in June 1918, with 18.83. It subsequently recovered somewhat, but in Aug. 1921 it stood only at 21.64. Of course this involved great losses for English residents and travellers, while the better value, obtained both in France and Italy, drew many to those lands.

BIBLIOGRAPHY, 1900-21.—In 1910 the 6th and final volume of the *Dictionnaire Géographique de la Suisse* (the first appeared in 1902) was issued at Neuchâtel, while in 1918 the same publishers began the publication of the *Dictionnaire Historique et Biographique de la Suisse*. (Both publications are issued in French and German.) H. Barth gave to the world in 1914-5 the three vols. (going down to the end of 1913) of his marvellous *Bibliographie der Schweizer Geschichte*. In the domain of constitutional history we have a new and revised edition (1914) of W. Burckhardt's *Kommentar der schweizer Bundesverfassung von 1874*; A. Heusler, *Schweizer Verfassungsgeschichte*, E. Hüs, *Geschichte des neueren Schweiz. Staatsrechts 1798-1848* (vol. I 1920); and W. Raustein, *Die Schweiz. Halbkantone* (1912). For very early Swiss history we have A. Schenk, *La Suisse Préhistorique* (1912); P. E. Martin, *Études critiques sur la Suisse à l'Époque mérovingienne, 554-715* (1910), and Marius Hesson (now the Bishop of Lausanne and Geneva), *L'Art barbare dans l'ancien diocèse de Lausanne* (1909).

The very best detailed history of the Swiss Confederation is that by J. Dierauer, entitled *Geschichte der Schweiz. Födergenossenschaft*, now complete in five vols. and published at 10th (vols. I and II, 2nd ed., 1913; vol. III, 1907; vol. IV, 1912; and vol. V, 1917) which brings the tale down to 1848;—a continuation is in preparation—there is also a French translation. F. Gagliardi, *Geschichte der Schweiz* (2 vols., 1920), is a new general Swiss history.

An important episode in Swiss history is narrated by E. Gagliardi, *Der Anteil der Schweizer an den italienischen Kriegen, 1494-1516* (vol. i., 1494-1509, 1919). Marie Louise Herkin's life of C. V. Bonstetten, 1745-1832 (1920) is a contribution to Swiss literary history of the 18th century. W. Oechsl's *Geschichte der Schweiz im 19ten Jahrhundert*, from 1798 (vol. ii. appeared at Leipzig in 1913, the work will be continued by E. Gagliardi), and J. Winger's life of Josef Zemp, 1834-1908 (1908), like E. Deriaz's *Un Homme d'Etat vaudois, Henri Druey, 1799-1855* (1920), and T. Weiss' life of Jacob Stampfli, 1820-1879 (1920), relate to modern Swiss history. In 1918 W. Oechsl published at Zurich a new edition of his *Quellenbuch zur Schweizergeschichte*.

In geology we have to note A. Heim, *Geologie der Schweiz* (appearing since 1919 in parts at Leipzig). In the domain of the fine arts vol. iii. of the *Schweizer Künstler-Lexikon* appeared in 1913, as did an extensive supplement to the work. The special works by J. Scheuber, *Die mittelalterlichen Chorstühle in der Schweiz* (1910) and by E. A. Stuckelberg, *Cicerone im Tessin* (1918) are also very useful works in this department.

In ecclesiastical history we have the fine monograph, *Angela-montana* (1914), and vol. ii. (vol. i. appeared in 1907) of J. G. Mayer's *Geschichte des Bisthums Chur* (1914), and vol. v. (1917) of E. Doumergue's *Jean Calvin*.

Another subject of great importance to Switzerland is treated of in H. A. Gurtner's *Zur Verschuldung der Schweiz. Hotelgewerbes* (1918), written by a Swiss hotel-keeper's son.

The following works refer to the Swiss Alps—Julien Gallet, *Dans l'Alpe Ignorée* (1910); E. J. P. de la Harpe, *Les Alpes Valaisannes et Les Alpes Bernoises* (1911 and 1915 respectively); and H. Dübi, *Die ersten 50 Jahre des Schweizer Alpenclub* (1913, also in French).

Turning now to the several cantons the following works deserve mention—

BASEL: R. Wackernagel, *Geschichte der Stadt Basel* (vol. ii. 1916, vol. i. appeared in 1907); A. Heusler, *Geschichte der Stadt Basel* (vol. i., 1917).

GENÈVE: L. Cramer, *La Seigneurie de Genève et la Masson de Savoie, de 1559 à 1605* (2 vols. 1912); H. Heyer, *L'Eglise de Genève 1535-1600* (1909); L. Blondel, *Les Faubourgs de Genève* (1919; vol. iii. 1918) of the *Recueil Généalogique Suisse*, W. Oechsl, *Les Cantons Suisses et Genève 1477-1815* (1915); and E. Doumergue, *La Genève des Genevois* (1914).

TICINO: Karl Meyer, *Leventina und Blenio von Barbarossa bis Heinrich VII.* (1911).

VALAIS: D. Imesch, *Die Walliser Landrats-Abtschiede seit 1500* (vol. i., 1500-19, 1916), and A. Buchi, *Korrespondenzen und Akten zur Geschichte des Kardinals Matth. Schiner* (vol. i., 1489-1515, 1920).

VAUD: B. van Muyden, *Pages d'Histoire Lausannoise* (1911), and *Recueil de Généalogies Vaudoises* (4 parts, 1912-20).

ZÜRICH: K. Dändliker, *Geschichte der Stadt und des Kantons Zurich* (3 vols., 1908-12). (W. A. B. C.)

SYDENHAM, GEORGE SYDENHAM CLARKE, 1ST BARON (1848-), British soldier and administrator, was born in Lincolnshire July 4 1848. He was educated at Haileybury and Wimbledon, and afterwards at the Royal Military Academy. In 1868 he entered the Royal Engineers, and in succeeding years served in various expeditions abroad, including the Sudan operations of 1885. The same year he returned to England, and was employed at the War Office until 1892, being at the same time secretary to the Colonial Defence Committee. He was also secretary to the Royal Commission on Navy and Army Administration. From 1894 to 1901 he was superintendent of the royal carriage factory at Woolwich. During all these years Sir George Clarke, who was created K.C.M.G. in 1893, had earned a great reputation, outside as well as inside his profession, as an authority on military questions, over and above his special subject of fortification. On his retirement from Woolwich, he was made a member of the important committee on War Office reorganization. In 1901 he was appointed governor of Victoria (Australia), and on his retirement in 1904 he became secretary to the Committee of Imperial Defence. From 1907 to 1913 he was governor of Bombay. He had been created G.C.M.G. in 1905, and in 1913 was raised to the peerage. He subsequently took a vigorous interest in many public questions, becoming chairman of the Royal Commission on Contagious Diseases (1913-5), chairman of the Central Appeal Tribunal (1915-6), and president of the National Council for Combating Venereal Diseases. In addition to his classic work on *Fortification* (1890; 2nd ed. 1907), his publications include *The Navy and the Nation* (1897) and *Imperial Defence* (1898), besides handbooks on military subjects.

SYKES, SIR MARK, 6TH BART. (1879-1919), English traveller and politician, was born March 16 1879, the only child of Sir Tatton Sykes, 5th Bart., of Sledmere, Yorks. He was educated

at the Roman Catholic public school of Beaumont College and afterwards at the École des Jésuites, Monaco, and Jesus College, Cambridge. He served in the South African War (1902), in 1904 became secretary to Mr. George Wyndham in Ireland, and in 1905 went to Constantinople as honorary attaché to the British embassy, remaining there until 1907. Before this, however, he had begun a series of travels and explorations, especially in Turkey and the Near East. He published several works dealing with his various expeditions, among them being *Through Five Turkish Provinces* (1900); *Dar-el-Islam* (1903); and *Five Missions of the House of Othman* (1909). He also prepared maps of the north-western region of Mesopotamia and of the southern districts of Palestine, for which in 1906 he was thanked by the Army Council and Foreign Office. His knowledge of these regions proved invaluable during the World War. In 1911 he was elected to Parliament for Central Hull as a Unionist, and in 1913 he succeeded his father as 6th Baronet. On the outbreak of war in 1914, Sir Mark Sykes raised a battalion of the Yorkshire Regiment, but did not proceed with it to France. He was sent on important special missions to Russia, Mesopotamia and Syria, and published in 1915 *The Caliphs' Last Heritage*. He died suddenly in Paris Feb. 16 1919.

SYMPATHETIC NERVOUS SYSTEM, in physiology (see 26.287) On studying the effects of stimulation of the sympathetic nervous system it appears that they are directed towards activating the body for fight or flight. The dilatation of the pupil increases the perception of light; the acceleration and augmentation of the heart-beat increases the blood supply; the constriction of the blood vessels in the visceral area raises the blood pressure, driving the blood from the digestive area, whose functions are simultaneously inhibited, into the skeletal and cardiac muscles, the lungs and the brain. The sweat glands are stimulated to cool the blood heated by increased muscular effort and the hairs are erected in many animals to render them more alarming. The "goose skin" experienced by man under emotional stress is similarly produced, though not now advantageous. Some emotional responses, like some bodily structures, are vestigial remains. The other division of the autonomic system, to which the name of parasympathetic has been given, serves the purpose of building up reserves and of fortifying the body against times of need and stress. Thus by contracting the pupil it shields the retina from excessive light; by slowing the rate of the heart it gives it longer periods for recuperation; it excites appetite and by promoting the assimilation and digestion of food it stores up energy. The sacral division of the parasympathetic is a mechanism for emptying, thus leading to greater comfort. The sympathetic is, therefore, katabolic, converting potential energy into kinetic, and facilitating outward manifestations of that energy, while the parasympathetic is anabolic, directing energy inwards, where it is stored up. When these two are distributed to the same structure their action is always antagonistic.

In pain, fear, rage and any intense excitement, the sympathetic neurons are brought rapidly into play and the action of the cranial division of the parasympathetic is inhibited. Anabolism is in abeyance and katabolism goes on unchecked. This is comprehensible, since these katabolic activities are defensive in origin and aided the primitive animal in its struggle with or flight from its enemy.

Of late it has been realized that each of these divisions of the autonomic system coöperates with its appropriate group of endocrine glands. The sympathetic group consists of the adrenals, the thyroid and the pituitary—each of which are accelerators of metabolism. The intimate relationship embryologically, structurally and functionally between the nervous and glandular elements is best illustrated by the adrenals. The medulla of the adrenals and the sympathetic ganglia originated from similar cells, preganglionic fibres end round both, and adrenalin, the secretion of the medullary portion, produces the same effect on any part as stimulation of the postganglionic fibres; an interesting example of parallelism between a nervous and chemical mechanism. Just as the preganglionic fibre stimulates the secretion of adrenalin, so adrenalin increases the postganglionic responses.

A similar reciprocity exists in the case of the thyroid; it is stimulated to secretion by the sympathetic and the secretion lowers the threshold to sympathetic stimulation. The existence of sympathetic secretory nerves to the pituitary has been shown, but there is no definite evidence of a reciprocal action of its secretion on the sympathetic.

The endocrine group which coöperates with the parasympathetic must be looked for chiefly in the glands of the alimentary tract and its annexes, since the building up of energy must ultimately be derived from the food. Gastric secretion is started by the appetite and the taste of food reflexly stimulating the organs, but it is continued by a hormone in the pyloric glands of the stomach which spur the fundus glands on to renewed effort. In its turn the acid gastric juice entering the duodenum acts on its mucosa to form secretion, which stimulates secretion of pancreatic juice. But the pancreas forms an internal secretion as well, which promotes the assimilation of sugar. Indeed, the metabolism of sugar gives a particularly good illustration of the general principle here laid down. Acting muscle requires three and a half times as much sugar as resting muscle, and the mobilization of sugar into the blood is a necessary preliminary to muscular effort. Accordingly sympathetic stimulation is found to produce this effect, through the adrenals, thyroid and pituitary, the secretion of each of which taken separately will lower carbohydrate tolerance and may excite glycosuria. On the other hand, the pancreas which is innervated by the parasympathetic has a precisely opposite effect, the antagonistic action of the glands being as definite as that of the associated nerves. Another example of this antagonism is seen in the continuous flow of pancreatic juice following removal of the adrenals, which can be temporarily inhibited by injection of suprarenal extract. Again, it is well known that adrenalin dilates the pupil of an excised eye but not of the intact eye of a normal individual. Therefore something inhibits the adrenalin effect. In depancreatized dogs adrenalin does dilate the pupil, and it has been found to do the same in patients suffering from pancreatic disease, since the normal antagonism of the pancreas to the adrenals is then lost. This pupillary response may also be present in hyperthyroidism, suggesting that the thyroid excess inhibits pancreatic activity, allowing adrenalin to show its dilator action unchecked.

The sympathetic nervous system, the endocrine glands and the gonads form a basic tripod entrusted with the duty both of the preservation of the individual and the continuity of the species. Their relationship is shown in disease as well as in health, and is reflected in many neuroses and psychoses. Disease is the resultant of some external action and of the reaction of the organism against it. It therefore draws on the defensive mechanisms and connotes a position of less stable equilibrium in which the body works with more friction. It may demand an increased supply of hormones to compensate for this, which may ultimately lead to exhaustion of the gland that provides it. In this way the balance between the endocrine glands is disturbed, either from overaction of a gland, or from its unopposed action through the loss of an antagonist.

The sympathetic-endocrine system is affected alike by toxic, nutritional or psychic factors, and is particularly likely to be injuriously influenced if more than one such factor is overtaking it. As this system has to defend us against internal foes, such as bacterial infections, as well as external enemies, we find that it plays an important part in the regulation of the body temperature. Since it has been shown that the cerebral vessels are remarkably impermeable to drugs and toxins as long as they maintain their integrity, it has become impossible to explain febrile reaction to infection by a central mechanism. When the activity of the thyroid and anterior lobe of the pituitary is diminished, less heat is produced. When increased production is required, the thyroid and adrenals give histological evidence of increased secretion. Cramer has found this both in fevers and after exposure to cold. He has also experimentally produced such changes by the injection of a drug which causes fever. Infections such as gas gangrene which do not induce a febrile reaction do not produce these changes. He has traced the adrenalin into the blood vessels, whereby sympathetic nerve endings all over the body will be stimulated. At the same time more sugar is poured into the blood, largely through thyroid activity. The oxidation of this sugar increases heat production. It has long been known that the adrenals may show marked signs of exhaustion after a severe infection such as diphtheria, while the thyroid may suffer after typhoid fever. Such exhaustion appears to be an important factor in the psychoneuroses of convalescence.

The influence of nutritional factors on the apparatus is seen in the way in which (1) pregnancy enlarges the thyroid and pituitary;

(2) vitamin defects cause enlargement of the adrenals and pituitary while causing some atrophy of other endocrine glands; (3) deficiency of assimilable protein in the food causes pellagra in which the adrenals suffer, while the sympathetic nervous system shows actual structural degeneration. While toxic and nutritional influences play chiefly on the glandular part of the apparatus, psychic factors naturally act primarily on the nervous part, though ultimately both parts will become affected, whichever is involved first. The sympathetic is the lowest level of the nervous system and retains several characteristically primitive features, such as peripheral ganglion cells, myenteric nerve nets, connector fibres lying outside the central nervous system, and urgent widespread responses, rather than accurately localized and discriminative ones. This is in accordance with the evolution of the nervous system for defense, and with the maintenance of this primitive function by the sympathetic. Pain has been shown by Trotter to be the specialization of the primitive sensation of lower animals, and fear might similarly be regarded as a specialization of a primitive emotion. It is to such sensation and emotion that the sympathetic nervous system preëminently responds. Both pain and fear are apt to become intense when the appropriate motor response is prevented, though they may not be appreciated when vigorous response is possible. Thus during the excitement of a fight neither fear nor pain may be experienced under conditions which would ordinarily induce them. In the civilized state the response appropriate to primitive man has often to be repressed. The effect of this repression may show itself either as an anxiety neurosis, at the psychic level, or at the sympathetic-endocrine level in certain affections of the associated glands, and in cardiac or digestive neuroses. Such repressions are particularly likely to be necessitated when the great instincts of self-preservation, reproduction and gregariousness, which relate respectively to the life of the individual, of the species and of the community, come into conflict with one another. The constant demand for adrenalin when sympathetic action is increased in fear and anxiety may lead to exhaustion of the gland. Addison's disease presents a clear-cut picture of adrenal deficiency in its symptoms of muscular weakness, low blood pressure, pigmentation and vomiting. Although this is due to organic changes, slighter degrees of a similar condition are now recognized and it has been suggested that this enters into many war neuroses and other functional states characterized by vasomotor instability, low blood pressure and myasthenia. Conversely, prolonged oversecretion by the adrenals must tend to raise blood pressure through the sympathetic, tending in turn to arteriosclerosis, with all its widespread effects. The well-known influence of anxiety in producing this condition can thus be explained.

There is a close association between the thyroid, the reproductive organs and the sympathetic. The thyroid tends to enlarge at puberty, marriage and in pregnancy, while myxoedema is most apt to occur after the climacteric. Amenorrhoea is common even in the minor degrees of hyperthyroidism. The effect of sympathetic irritation in producing thyroid enlargement and Graves' disease is now recognized. Cushing showed that if in cats he sutured the phrenic nerve to the cervical sympathetic so that every respiration stimulated the latter, he could produce the symptoms of Graves' disease. The influence of distressing emotions in producing hyperthyroidism was well shown during the air-raids on London during the World War. Epidemics of Graves' disease also followed the Kishinev massacres and the San Francisco earthquake. Again, if a distressing emotion has a matrimonial origin, it is particularly likely to induce Graves' disease, for here each limb of the basic tripod is involved. The disease has been compared with a state of continuous fear, a description which tallies with its general appearance.

The pituitary body also shows the two-fold association with the reproductive organs and the sympathetic nervous system. The anterior glandular part has an effect on temperature, the growth of bone and skeletal tissues and the reproductive organs. The intermediate lobe influences carbohydrate metabolism, while the secretion of the posterior lobe is mainly a stimulant to plain muscle and to the secretion of milk. The effect of the secretion of the posterior lobe on diuresis is still a matter of controversy, but it is clear that disease of the posterior lobe is often found in diabetes insipidus and that stimulation of the sympathetic nerves to the gland will cause polyuria. Probably hysterical polyuria is thus produced.

It is also clear that some cases of glycosuria are of sympathetic nervous origin, the physiological mechanism by which this can be brought about has already been explained. Diabetes is characterized, like sympathetic stimulation, by an exaggerated katabolism. This shows its effect first on the most abundant and most easily metabolized of the food-stuffs, the carbohydrates, which are also essential for muscular action, to which sympathetic stimulation should normally be a preliminary. Sympathetic stimulation induced by various disagreeable emotions will increase metabolism generally and specially lower carbohydrate tolerance. The influence of excitement and emotion in causing glycosuria is well recognized. It is commonest in Jews, a notoriously emotional race. When stocks go down in New York, says Crile, diabetes goes up. Temporary glycosuria occurred in a number of men who merely watched a football cup-tie without participating in it. Glycosuria has been, unfortunately, comparatively common in young officers entrusted with heavy responsibilities during the war. Singer and Clark have

recorded two cases in which there was alternation between glycosuria and the exhibition of mental symptoms, as if the emotional discharge asserted itself either at the metabolic or the psychic level but not at both.

Finally, the inhibitory effect of the sympathetic on the digestive processes must be remembered. Fear checks the secretion of saliva, anger stops the secretion of gastric juice. Depressing emotions acting through the sympathetic check the peristalsis of the stomach while closing the pyloric sphincter, thus leading to a dilatation of the stomach. A similar inhibition of intestinal peristalsis may occur, leading to intestinal stasis. This in its turn will lead to a drag on the sympathetic nerves in the mesentery, increasing their inhibitory effect. Thus a vicious circle is established and the persistent intestinal toxæmia that results may produce organic changes in many structures, including the group of endocrine glands which cooperate with the sympathetic.

The consideration of diseases produced through the agency of the parasympathetic lies outside the present topic, except in so far as the vagus may overact from a loss of balance produced by diminished sympathetic action. Suffice it to say that laryngeal spasm, asthma, slow or irregular action of the heart, low blood pressure, hyperchlorhydria, spastic constipation and a liability to skin disturbances of the vasodilator type are among the symptoms evoked. Since febrile reaction to disease is a function of the sympathetic, which is antagonistic to the parasympathetic, we find that those subjects with an overacting vagus do not react well to infections and, indeed, show an abnormal sensitiveness to many foreign proteins. Their tendency to undue anabolism is sometimes indicated by their tendency to flabbiness of the tissues and overgrowth of lymphoid structures. A curious point is the occurrence of sweating, since the secretion of the sweat glands is under the control of the sympathetic. But a similar discrepancy is seen in the action of a vagotropic drug such as pilocarpin.

In assessing the effects of the sympathetic nervous system in disease, it must be borne in mind that we have very little knowledge of its morbid anatomy, though a beginning has been made in the study of pellagra. The evidence so far mainly relates to function and were our knowledge of its structural alterations at all comparable to what we know of organic changes in the spinal cord, we should be on firmer ground. But enough has been learned to show that the sympathetic plays a large part in the regulation of the internal viscera, and, through the endocrine glands, in general metabolism. The balance between these glands determines to a large extent both the racial and individual characteristics. Climatic influence has a profound effect through the skin on the sympathetic nerves and hence on the endocrine glands. The development of protective pigment is an important method by which the sympathetic-endocrine system can react to this, and the unadaptability of albinos in this respect is well known. Thus physical environment can influence both temperament and structure, and the sympathetic-endocrine system must have played a large part in developing the variability of man into different races.

Involved in a subconscious plane the sympathetic nervous system remains for ever beyond the control of the will. Taine quotes an instance which, while apparently contradicting this, proved on further inquiry to support it. This was the case of a man who could voluntarily dilate his pupils, who could cause the pilomotor muscles to raise the hairs on his arm, and who could at will produce the phenomenon of "goose-flesh" in various parts of his body. When closely questioned he admitted that the effects were produced not immediately by his will, but always by the intermediation of some association called into being by him. Thus when dilating his pupils he always imagined himself looking far into space, under which conditions the pupil does dilate. For the goose-flesh effect he would picture to himself his arm plunged into ice-cold water, and the goose-flesh appeared. Various associations produce autonomic effects without our will, and it is reasonable to infer that, if we can recall these associations through our will, the same autonomic effects will be produced.

The higher centres of the brain show their influence on the lower chiefly in the direction of inhibition. The highest organism is the most self-controlled, but the sympathetic cannot be thus controlled. The will can only help in so far as "it can make our voluntary activities harmonize with our environment." The emotional apparatus remains, as McDougall has pointed out, the most unchanging part of our nervous equipment, though the stimuli to which it responds may vary enormously in different individuals. But once the response occurs, it is extraordinarily true to type. This is comprehensible since the apparatus retains so many features of the primitive nervous system. (W. L. B.)

SYNDICALISM.—"Syndicalism" is the name given to a form of socialist doctrine elaborated by, and born from the experience of, the members of the French *syndicats* or trade unions. On the one hand it is a body of social doctrine, or theory of social organization, on the other it is a plan of action for the realization of this ideal. Of all the social theories competing for existence it is the most purely proletarian in origin. One writer indeed has de-

scribed it as "working-class Socialism" (*le socialisme ouvrier*) in contradistinction to the types of socialism originated and propagated by middle-class "intellectuals." Without unduly stressing the importance of this fact, it may be said that syndicalism is that form of socialist theory which regards the trade-union organizations, entirely proletarian in origin and direction, as at once the foundations of the new society and the instruments by which it is to be erected.

The syndicalist starts from the assumptions common to most schools of socialist thought. He affirms the inherent injustice of the wages system and the fundamental immorality of capitalist society, which is based, in his belief, on the exploitation of labour. He accepts and pushes to its logical conclusion the Marxian dogma of the class war; he therefore affirms that solidarity of interests does not, and cannot, exist as between employer and employed, between capitalist and wage-earner. From these premises he draws the usual socialist conclusion, namely, that individual ownership of the instruments of production must be abolished and communal ownership and control substituted for it. But at this point syndicalism and socialism (as usually understood) part company. Whereas the orthodox socialist demands control by the consumers acting through the State and its dependent organs the municipalities, the syndicalist demand, until very recently, was for producers' control, acting through the organizations of their own creation—the trade unions. This is the essential feature of syndicalist theory, that which differentiates it from other revolutionary schools of thought. The arguments usually employed by its advocates may be briefly set out.

State organization and control of industry are, in their view, incompatible with true working-class emancipation. The State is, and must be, an instrument of class domination, it is indeed "the executive committee of the capitalist class." It exists to defend the interests of that class, and is consequently as much the enemy of labour as capital itself. To extend its powers would be to twine the bonds of wage slavery ever more firmly about the workers' limbs. The State is, however, hopelessly wedded to an uncreative bureaucracy, incapable of initiative and ignorant of industrial technique. Its control, even if it were benevolent (which the syndicalist denies it could be), would necessarily be despotic and inefficient, the spirit of routine would combine with inexperience to crush out the possibility of economic progress. Here, as will be seen, the syndicalist endorses the ordinary individualistic criticism of State socialism. Producers' control, exercised through the *syndicats*, would, on the other hand, combine freedom with efficiency. Every worker would participate directly in the government of his industry, he would thus enjoy the substance of democracy instead of the shadow offered him by the *bourgeois* State. Moreover, the worker would be led to identify his personal interests with the successful conduct of the industry; he would have a pride in his work which would manifest itself in improved quality and greater output, thus producers' control would be justified both on human and economic grounds.

The form of social organization in which this ideal could be realized was, until recently, conceived somewhat as follows. The unit of organization would be the local *syndicat*. This would be brought into touch with the local groups by means of the *Bourse du Travail*, the present function of which is to act at once as an employment agency and a general centre for trade-union activities. When all the producers were thus linked together by the *bourse*, the administration of the latter would be able to estimate the economic capacities and necessities of the region, could coördinate production, and, being in touch through other *bourses* with the industrial system as a whole, could arrange for the necessary transfer of materials and commodities, inwards and outwards. A species of "economic federation" would thus replace the structure of capitalist industry, with which would necessarily disappear the political and administrative machinery of the State. Two features of this Utopia need to be emphasized. Consumers as such were excluded from any share in industrial control, and a localized system of industry was envisaged.

This latter feature was a direct reflexion of French economic circumstances; both industry and trade-unionism were much

more local in range than in other and more highly developed countries. But the movement towards large-scale organization which has so profoundly affected every aspect of economic life in recent years has produced a corresponding modification in syndicalist ideals. At the same time, it has begun to be recognized by the theorists of the movement that the consumers' point of view cannot wholly be disregarded. The experience of the World War has also had its effect. The Congress of Lyons, therefore, in 1919 was moving with the times when, in demanding the "industrialized nationalization of the great services of modern economy: land and water transport, mines, water-power, and credit organizations," it defined "nationalization" as "the confiding of national property to the interested parties, namely, the associated producers and consumers." This clearly envisages organization on a national scale and the participation of consumers' organizations in control.

Syndicalist theory starts, as has been said, from the idea of a class war which must be waged relentlessly till a complete social transformation has been accomplished. The essential weapon in this struggle is the power of the organized workers. As the cause of the conflict is economic it must necessarily be fought out in the economic sphere. Syndicalist congresses have persistently repudiated political action, and pinned their faith to a general strike as the grand instrument of social revolution. This reliance upon industrial or "direct" methods of action flows necessarily from the fundamental notions of syndicalism as to the nature of the State, and also from strictly practical considerations. Outside the mine or factory, workmen hold divergent religious or political opinions which make effective mass action difficult, if not impossible. Inside, the nature of their employment gives them a sense of solidarity which overrides minor differences and bands them together in the *syndicat* for common defence, to persuade them to pass from the defensive to the offensive is the syndicalist's task, and in the accomplishment of this political labels and controversies would be a hindrance. Moreover, the political party is not, and cannot be, a class organization. The Socialist parties swarm with men of middle-class origin whose only bond with the workers is the slender one of opinion. In any event, the political party is an inefficient instrument for revolution, it can only operate effectively at electoral periods, and even then the mass of voters do nothing more than cast a ballot and return to their customary apathy for a term of years. Political action does nothing to rouse them from that apathy, to inspire them with revolutionary *élan*, to train them to initiative and independent thought. On the contrary, it asks for nothing better than docile followers of self-constituted leaders. The strike, therefore, is the characteristic syndicalist weapon. However limited in its scope and object, it is an educative experience; successful, it inspires the workers with a sense of power, unsuccessful, it impresses upon them the servility of their lot and the necessity for better organization and wider aims. Thus every strike is a preparation for the revolutionary "day," when the workers, or a fighting minority of them (for syndicalism repudiates as *bourgeois* the dogma of the sacredness of majority rule), shall seize the instruments of production by an "expropriatory" strike. In the meantime, they are working out from day to day, in the ordinary course of their employment, the ethics and the jurisprudence of the new social order.

The strike, of course, is not the only weapon in the syndicalist armoury. Various other means of waging the class war, known collectively as *sabotage*, are both preached and practised. These range from bad or slow work to the *grève perlée* (destruction of goods or machinery) and the *chasse aux renards* (assaults on "blacklegs" or *jaunes*). It is fair to say that many syndicalist leaders criticize these methods as destructive of the worker's moral and technical competence.

Syndicalism is essentially French in origin and reflects French working-class experience and conditions of life, nevertheless the history of Great Britain shows interesting foreshadowings of it. The idea of industrial self-government by the producers attracted for a time the mobile mind of Robert Owen; and the Grand National Consolidated Trades Union of 1834 was an attempt

to realize it in practice. James Morrison, a young self-taught operative builder, seems to have originated the syndicalist conception of class antagonism on the part of the working-classes (see Max Beer, *History of British Socialism*). The Building Trades Union had developed the same notion in the previous year (S. and B. Webb, *History of Trade Unionism*). The plan of a general strike—originated by one Benbow—for a time, under the strange title of the "Sacred Month," made part of Chartist propaganda. There is no evidence, however, that these projects had any echo on the European continent. The syndicalist idea, as understood in France, may be said to have originated in the discussions of the International Working Men's Association. A French delegate to the Congress of Basle in 1860, for instance, prophesied that "the grouping of different trades in the city will form the commune of the future" when "government will be replaced by federated councils of *syndicates* and by a committee of their respective delegates regulating the relations of labour—this taking the place of politics" (Levine, *Syndicalism in France*). The collapse of trade-unionism in France after the sanguinary suppression of the Communalist insurrection in 1871 had as a necessary consequence the submergence of these ideals for a considerable period, and only a combination of favouring circumstances brought them once more to light. Among these the discontent of the organized workers with Socialist politics, and the anarchist propaganda of a general strike, may be particularly mentioned. These influences manifested themselves with increasing strength during the 'nineties in the two great labour organizations of the period—the General Confederation of Labour (or "C.G.T." under its French initials) and the Federation of *Bourses du Travail*. The secretary of this latter organization, Pelloutier, did more perhaps than any other individual to work out the characteristic doctrines of syndicalism and spread them among his fellow-workers. When these two bodies joined forces in 1902, trade-unionism in general and syndicalism in particular received an immense accession of strength, and the doctrine subsequently remained—in spite of the efforts of political socialists to capture the *syndicates* for their own purposes—the characteristic expression of French revolutionary idealism.

As such, it has inevitably received much attention from observers and writers drawn from other social classes. Of these the best known is Georges Sorel, but it is a complete error to suppose that he was the originator of syndicalism, or that he has had much influence on working-class opinion. The difficult form of his writings, with their frequent obscurity and lack of continuity, would alone have made this impossible. Sorel's adaptation of the Bergsonian doctrine of the "*élan vital*" to syndicalist purposes, and his theory of "social myths" (of which the general strike is one), have had considerable influence upon intellectual circles, but have affected no more than a fringe of working-class readers.

Syndicalist doctrine has had considerable influence outside France. In the United States, a movement of somewhat similar character arose with the organization of the Industrial Workers of the World. The Chicago Convention of the I.W.W. in 1905 drew up a declaration, the preamble of which affirmed the reality of the class struggle, embodied the theory of social organization which it involves and further made a plan for the realization of this ideal—

"The unit of organization industrially is the workshop or Yard Committee, wherein the workers are organized as workers, irrespective of craft, grade, or sex. These Committees are coordinated by the formation of Works or Plant Committees, composed of delegates from each Workshop or Yard Committee. The Plant or Works Committees are coordinated by delegates from each of these Committees, in a village, town, city, or district, forming a Workers' Council, in which there are also delegates from the residential committees, these latter being the units of the social aspects of the organization."

The above scheme differs very little from the general theory of syndicalism in France, and presents a simple parallel to the shop-stewards' movement in Great Britain, which indeed was based upon it. The influence of the I.W.W., it may be noted, was largely confined to the alien immigrant workers: it never penetrated the American Federation of Labor to any serious degree.

The influence of these ideas on the trade-union movement in Great Britain and Ireland has been very pronounced, though they have taken a different direction, modified by the traditional, conservative instinct of the British working-class. In Great Britain the real cause of the permeation of certain unions by syndicalist ideas was the absorption of trade-union leaders in administration or in politics, which caused them to lose touch with the rank and file. Especially is this the case with regard to the miners, the railwaymen's unions and the engineers.

Daniel de Leon was leader of the Socialist Labour party in the United States from 1880 onwards, and his writings influenced British socialist thought, particularly in the Clyde and in the mining valleys of S. Wales. Though not a syndicalist in the strict sense, he advocated organization by industry and the general strike. It is significant that 1903 saw in England the secession of the Socialist Labour party from the Social Democratic Federation. After that date, in addition to the growing educational influence of the Independent Labour party (though this was never syndicalist), was seen the promotion of the Workers' Socialist Federation, the British Socialist party (in the post-war period) and the Communist League, all of which advocated practically the same structure of organization and policy. They all agreed in a lack of faith in political action, though not always refusing to utilize it, but their real *politisik* was industrial action. After the Russian Revolution of 1917, they secured greater prominence; they became the stormy petrels of the labour world in Great Britain, and their effect on the political action of the Labour party was seen in the Council of Action in Aug. 1920.

In England, between 1900 and 1910, there was a growing dissatisfaction among the rank and file with political action, despite the fact that the influence of the Labour party in the House of Commons secured the trade-union movement freedom of industrial and political action by the Trades Disputes Act of 1906 and the Trade Union Act of 1913 to a greater degree than ever before, it was felt by the far-sighted among the rank and file that a speeding up was necessary, and State collectivism as a way out towards industrial democracy was discredited. James Connolly, the Irish Labour leader who was executed after the Easter rising in Ireland in 1916, started a similar organization to that of Daniel de Leon on the Clyde in 1905. In his pamphlet *Socialism made Easy* he enunciated the syndicalist principles "that they who rule industrially will rule politically," and that "the functions of Industrial Unionism is to build up an industrial republic inside the shell of the political state, in order that when the industrial republic is fully organized it may crack the shell of the political state and step into its place in the scheme of the universe." Tom Mann, while in France and Australia, which had imported the ideas of the I.W.W. from America, was also powerfully influenced by the same theories, while on the Rand, in S. Africa, a small but very influential group of leaders was working out the structure, forms and policy of a movement similar in character. In 1910 Tom Mann preached the new faith in all the big industrial centres and rapidly won many followers. Workmen had refused to follow their orthodox leaders from about 1908, as they felt that the trade union of the old Liberal-Labour school was behind the times. The Plebs League was founded by a group of labour students in Ruskin College, Oxford, about the same time, and in 1909 these seceded from Ruskin College and founded first a labour college in Oxford and then moved to London as the Central Labour College, financed by the S. Wales miners and the railwaymen. This educational movement organized classes in every mining area in S. Wales, led by tutors from these two colleges, and influenced largely by the new ideas. A similar movement took place on the Clyde, in the great ship-building centres like Barrow, Birkenhead, and Pembroke Dock, and also in inland engineering centres like Coventry and Sheffield. Then followed the railway strike of 1911 and the great coal strike of 1912. It is quite clear that the National Union of Railwaymen and the Miners' Federation of Great Britain became organized as two of the most powerful unions in consequence of the new thought, not because their leaders had adopted syndicalism in the form taught by de Leon and the French group of

thinkers, but because they adapted it in the peculiar British way; they made it practical and definite; they shaped it in alliance with the political and trade-union structure of Britain. They disagreed with the syndicalist view of the State, but they recognized the driving power of the theories that stated "that political power is a reflex of industrial power." The transport workers soon had a similar federation, and after the strikes of 1911 and 1912, and the Irish transport workers' strike of 1913, the Triple Alliance (of railwaymen, transport workers, and miners) was formed in 1915. The failure of this last to function during the miners' strike in the spring of 1921 discredited "direct action," and the British labour movement swung back towards constitutional and parliamentary methods.

SYNGE, JOHN MILLINGTON (1871-1909), Irish dramatic author, came of an Anglo-Irish family, which had contributed several bishops to the Irish church. He was born near Dublin April 16 1871. A delicate child, he was left much to himself, and as a youthful member of the Dublin Naturalists' Field Club took long rambles over the Dublin and Wicklow hills. At Trinity College, where he graduated in 1892, he obtained prizes in Irish and Hebrew, and he knew something of several modern languages. At this period his chief interest was in music and he gained a scholarship in counterpoint and harmony in the Royal Irish Academy of Music. A sonnet, moreover, contributed to *Kol-tabos*, shows not a little of the accomplishment of verse, as well as his innate passion for primitive things. During the next few years (1893-8), Synge travelled in Germany, Austria, Italy, finally making Paris his headquarters. He managed to spend a third of the year in Paris, a third in the W. of Ireland, and a third in London or Dublin. W. B. Yeats found him in Paris (1898) preoccupied with theories of language and literature, and advised him to return to Ireland. He went to the Aran Is., where he shared the life of the islanders, and he gave an account of it in a series of sketches afterwards collected in the volume, *The Aran Islands* (1907). In these and other sketches of the same period he had not quite shaken off the obsession of "stylism," and still had a wish "to do for the W. of Ireland what Pierre Loti had done for the Bretons." Gradually, however, Ireland got hold of him, and, turning to the dramatization of incidents in the life he now knew intimately, he began to elaborate, partly from his note-books and partly from the writings of Lady Gregory and Dr. Douglas Hyde, that richly imaginative though largely artificial dialect of Anglo-Irish which he carried to its furthest capacities. The Abbey theatre was opened towards the close of 1904, with Synge as one of the directors. He had already produced two one-act plays, *In the Shadow of the Glen* and *Riders to the Sea* (1903), of which the first had acquired some notoriety for the author as an affront to Irish morals; he had also written a farcical play, *The Tinker's Wedding*, which proved a failure when acted (1909) after his death. The beautiful three-act play, *The Well of the Saints*, produced before a few dozen people in the early months of the Abbey (1905), was regarded as a new affront; and in Jan. 1907, rumour having got about of its subject matter, the performance of *The Playboy of the Western World* was interrupted by an organized disturbance which continued night after night for a week. This affair, when the merits of the play came to be known, made the fame of the Abbey theatre. Synge's health was now shattered, and with

death in prospect he worked at his fine play *Deirdre of the Sorrows*, all but completing it before the end came on March 24 1909. Just before he had collected his curious *Poems* (1909).

Synge appeared at a peculiar moment in the development of Irish literature, which had begun to address a largely increased public, blended of the two main elements of the population. By descent and culture he was of the Anglo-Irish stock, and he really saw the Irish subject matter in the detached spirit of an artist. It was probably something like this that part of his audience detected in the *Playboy*, and it caused his work for a while to be rejected in his own country. Time, however, has already proved the depth of Synge's insight into the soul of peasant Ireland. The *Playboy* is by general consent his masterpiece. In this play, the fantastically rich imagery of his dialogue, which elsewhere has often a somewhat monotonous effect, has full dramatic justification; the play has even, like *Hamlet*, the supreme mark of vitality, that it conveys the suggestion of a permanent human enigma. There are good critics, however, who assign the highest place among his works to *Deirdre*.

A collected edition of Synge's works, in four volumes, was published in 1910. In *John Millington Synge and the Irish Theatre* (1914), M. Maurice Bourgeois has given, in great detail, an account of his life and writings, and there is a critical study of him by P. P. Howe (1912).

SYRIA (see 26.305) —The greater part of the decade 1911-21 was a period of depression and distress in Syria, which, in common with the rest of the Ottoman Empire of which it then formed part, suffered from the interruption of commerce and the war-time exactions consequent upon the Italo-Turkish, the Balkan and the World Wars in an almost unbroken succession from 1911 until 1918. Although only for a brief time an actual theatre of hostilities, Syria, which had escaped with a slight bombardment of Beirut in Feb. 1912 during which a Turkish gun-boat was sunk in the harbour by an Italian squadron, was particularly exposed to military requisitions and exactions.

Even before the entry of Turkey into the World War involved the Levant ports in a fresh blockade (Nov. 1914) the coastal population had begun to migrate inland from fear of enemy landings, and the whole country was disorganized by the pressure of refugees on the one hand and of the military preparations for an invasion of Egypt on the other, while the civil population was much excited by the shameless propaganda conducted by German agents who sought to inflame Moslem prejudice against Christians all over the country. The Minister of Marine, Ahmad Jemal Pasha, who was also in command of the IV. Army and governor-general, conducted the government of the province in such a way as to give rise during a long period to the suspicion that he aimed at imitating Mehemet Ali in founding for himself a semi-independent viceroyalty; and his autocratic exactions and high-handed measures did much to pave the way for the final revolt against Turkish authority, which caused its collapse when the battles in Palestine in Sept. 1918 had broken the front.

In the subsequent operations Syria was overrun rather than conquered. Damascus fell to the British and Arabs on Oct. 1, Tyre was taken by the British on Oct. 4, Beirut was seized by a French squadron on Oct. 5 and occupied on Oct. 7 by British troops, which took Homs on Oct. 16, Tripoli (Tarabulus) on Oct. 18, Hama on Oct. 21, while the Arabs took Aleppo on Oct. 25 and the French occupied Alexandretta on Nov. 10.

Immediately after the liberation of Syria Gen. Allenby set up an administration of Occupied Enemy Territory in accordance with "the Laws and Usages of War" laid down by international agreements embodied in the Hague Convention. In order to comply as far as possible with the divergent policies to which the British Government had committed itself he confided those areas which had been liberated chiefly by Arab troops to "O.E.T.A. East," with Arab administrators under a chief administrator at Damascus—Ali Riza Pasha or Rikabi, while the Lebanon, the littoral N. of the Ladder of Tyre, and as far as Bab Yunis N. of Alexandretta, was under Col. P. de Piépape as chief administrator O.E.T.A. North in Beirut with French officers. Later, when Cilicia was occupied in conformity with the Armistice

which came into effect on Nov. 1 O.E.T.A. in Beirut became O.E.T.A. West and Cilicia was controlled by a new O.E.T.A. North under the French Col. Brémont.

From the very first the French had considerable difficulties to face, as Arab Nationalism and the idea of Syrian independence based upon the doctrine of self-determination both greatly influenced the civil population, which was, moreover, puzzled in that French officers were engaged in administering the country on French lines and conducting a French propaganda, when it was notorious that British troops had liberated the country and were still occupying a great part of it, and that the Arab administration in Damascus was anxious to lean on the British alliance and to ignore as far as possible the existence of the Sykes-Picot Agreement which had divided the country into arbitrarily defined spheres of influence regardless of the claims of the Arabs. Colonel de Piépape was, moreover, much hampered by the limited selection of French officers from whom he had to pick his administrators. Furthermore, Syria being a comparatively rich and civilized part of the Ottoman Empire and inhabited almost entirely by non-Turks had been particularly exposed to the exactions of the Turkish army and Government, and her population had been greatly exhausted by military conscription, political deportations, voluntary flight of refugees and by the ravages of locusts, starvation and disease. Yet Syria was unable to benefit to any great degree from the presence of the British army, as had Palestine; few military roads were made—except the remarkable rock-cut carriage-way across the face of the Ladder of Tyre (Ras en Naqura) which was made by Sir Valentine Fane's 7th Indian Div—little local labour was employed, and charitable contributions for the help of the civil population of Syria were the less readily forthcoming as it had none of the religious and sentimental glamour attaching to the Holy Land.

With the withdrawal of the British Army of Occupation from O.E.T.A. North and West which began on Nov. 4 1919 and ended on Jan. 19 1920 the difficulties of the French were greatly enhanced, as their own troops were hardly numerous enough to cope with the forces of disorder which began to raise their heads almost immediately. Attempts to enforce French authority were met with armed resistance. Certain of their agents played them false, and both in Cilicia and Syria Gen. Gouraud, who had become High Commissioner in Beirut in Oct. 1919, had to cope at once with Turkish Nationalist plots directed from Angora, panislamic agitation, anti-Armenian traditional hatred and Syrian and Arab Nationalism. Active troubles soon began, the Damascus administration, now controlled by the Emir Faisal, had little real authority over the semi-independent tribes which were plentifully supplied with rifles, either issued to them for war against the Turks, or captured weapons, and it was itself harassed by the conflicting policies of the Syrian extremists who resented the presence of the Arab "Patriarchalists" from the desert, and of the Hejaz Arabs who maintained that Syria was but a province conquered by them in war and lawfully at their disposal. The Emir had, moreover, to keep the peace with his French and British allies in the face of a growing anti-European spirit which was hostile to the French schemes for controlling Syria and indignant at the British attitude towards the Jews, while Syrian Nationalists resented the partition of the country between two foreign Powers and inclined towards anybody—even the once hated Turks—who offered hopes of driving the Europeans into the sea.

Baalbek was the scene of the first fighting between the French and Arabs—at Christmas 1919. In Jan. 1920 the French were attacked near Quncitera and in the Merj Iyun. Later in the month their troops were engaged in the Latakia (Ladigiye) district, and while they were able to recover Baalbek before the end of Jan. their garrison at Alexandretta was attacked in Feb. On March 1 the Jewish colony at Tell Hai, near Metulla, in what was then the French sector of Upper Galilee, was raided by Arabs. On March 8 the Syrian National Congress, sitting in Damascus, under the influence of impatient extremists, proclaimed the Emir Faisal as King of Syria, and placed him in an extremely difficult diplomatic position. In the face of the extremists he

was unable to hold back, and he organized a Syrian Cabinet under Riza Pasha and did his best to enforce discipline throughout his dominions where compulsory military service had been reintroduced on Dec. 21 1919. The authority of Damascus was, however, unable to restrain the outbreak of Arab Nationalist enthusiasm which the formation of the kingdom of Syria aroused. Antioch was taken from its small French garrison on March 20, there was anti-European trouble from the Amanus to Jerusalem (see PALESTINE), and Arab officers entered into renewed relations with the Nationalist Turks of Angora. As early as Dec. 11 1919 Ramadhan ibn Shalash, the Arab governor of Raqqa, instigated by Angora, had made common cause with a Kurdish freebooter, Ibrahim Pasha Milli, and had attacked Deir ez Zor, from which, although in the French sphere of influence, the British had not yet withdrawn. The Emir Faisal immediately dismissed Ramadhan, but he became contumacious, declined any longer to recognize the authority of Damascus and openly adhered to the Nationalist Turks. His Arab successor in Raqqa, Maulud Pasha, was equally disloyal, and throughout the summer disturbances in both French and British areas were actively fomented by him and other disobedient adherents of the Damascus Government.

More vigorous steps were taken by the Nationalist Turks of Angora. Not content with conducting a campaign of extermination against the Armenians in Cilicia where the French were not strong enough militarily to occupy the whole province in the face of the formidable Turkish forces operating against them and the Armenians, the Government of Angora invaded northern Syria itself. Aintab was attacked in strength on April 1 1920. It was relieved by a French column with some difficulty on April 15-16, but, when the relieving troops were withdrawn on April 28, the siege was resumed on April 30. It was relieved a second time on May 22, and an armistice was concluded on May 29 by which the French evacuated the citadel and established themselves in a fresh position. They were again attacked by the Turks and relieved for a third time on Aug. 11. This time the French were strong enough to attack in their turn, although unable entirely to invest the Turks, who had occupied the citadel as part of their position. After long-drawn operations, during which the Turkish mines in one of the piers of the great bridge of the Bagdad railway over the Euphrates at Jerablus were exploded by lightning and two spans of the bridge wrecked, the French were successful, and Aintab was once more made safe on Feb. 10 1921. During this period its pop. is supposed to have decreased by some two-thirds to 25,000. Nor were the disturbances in the N. confined to the Aintab area, apart from the campaign in Cilicia. Nationalist Turks and Syrians at the beginning of Dec. raided as far S. as Jebel on the coast 14 m. S. of Latakia, and farther E. a force of Nationalist Turks established themselves near the newly fixed boundary between Syria and Mesopotamia and tried to stir up unrest among the desert tribes.

In the S. the existence of an independent state at Damascus with Nationalist aspirations to absorb all Syria and the Lebanon, and unwilling to admit French influence or recognize any French mandate, was likely to prove an uneasy neighbour—the more so as the Emir Faisal had declined on two occasions (March 27 and May 8) to repair to Paris at the invitation of the Allies to explain the situation. The Emir maintained that it was only by remaining at Damascus that he could hope to restrain the more extreme Nationalists from launching a wholesale attack upon French territory. As soon, therefore, as Gen. Gouraud had an adequate force at his command with which to enforce the authority given to France as Mandatory for Syria on behalf of the League of Nations, he made ready to impose it upon Damascus, when in June 1920 the Emir Faisal was beset by difficulties. Himself one of the Ashraf, a son of the King of the Hejaz, he found it increasingly difficult to restrain the Nationalist Syrians, the pro-Turk panislamists and the Patriarchalist tribesmen who were traditionally hostile to any authority which sought to stand between them and their prey in the cultivated lands. In June the Cabinet of Riza Pasha fell, largely on the question of the relations between Syria and the Europeans—particularly the French, and Hashim Bey Attassi took office. At that time

in the discussions of the budget in the French Chamber it appeared that France, while proposing to allot some £3,700,000 for the expenses of the High Commissionership of Syria and some £440,000 for propaganda to be directed against the extremist doctrines of those opposed to her rule, was ready to grant a subvention of £800,000 to the Emir Faisal provided that he co-operated whole-heartedly in the execution of the Mandate. The Emir was, however, in no position to do so, owing to the intractability of the Nationalist leaders who threatened to depose or murder him if he ventured to abate in any way from the extreme of their ambitions, wholly incompatible with any foreign Mandate. At the same time the economic situation of Syria was bad, and the taxes were extremely high—for example, the camel tax in Syria was £E3 (£3 1s. 6d.) per beast as against 1 rupee (1s. 4d.) per beast in Mesopotamia, and the sheep tax was 36 P.T. (7s.) against 8 annas (8d.)—and were, moreover, farmed, owing to the absence of the necessary fiscal machinery for ensuring official collection. Thus the Emir's Government was regarded with suspicion by the Nationalists and those who were opposed to any accommodation with France, or indeed any European Power.

On July 14 1920 Gen. Gouraud informed the Emir that French authority was to be enforced and that he would assume control of the Syrian railways—hitherto run by the Arab administration, parts of which had not been working since January. This information was none too soon, as it was known that the Arab general, Rushdi Bey, in command of the 3rd Arab Div. and governor of Aleppo, who had formerly been in the Ottoman service, was in active communication with the Nationalist Turks of Angora for the purpose of arranging joint operations against the French. Almost at the same time Gen. Gouraud found it necessary to arrest nine members of the Administrative Council of the Lebanon, apparently for conspiring with Syrian Nationalists to make it impossible for France to exercise her Mandate.

The Emir Faisal was willing to comply with Gen. Gouraud's wishes, but the Syrian Nationalists, miscalculating their strength, opposed the advance of Gen. Goybet's column which was sent to occupy Damascus. They even attacked the Emir Faisal, delayed the final message of submission sent by the Emir and his Cabinet to Gen. Goybet, and by ill-judged hostilities compelled the French to defeat them smartly at Khan Meisclun on the road through the mountains N.W. of Damascus on July 24, and to enter that city next day as conquerors rather than as protecting allies, thus bringing about the downfall of the Emir, whom the French held responsible for the resistance of the Nationalists although it had been offered in defiance of his authority and policy. The Emir's last Cabinet fell with him, and the French, who inflicted a fine of £5500,000 (10,000,000 frs.) upon the country, caused a new administration to be formed under 'Ala ed Din er Rubi, while the Emir Faisal and his family withdrew from Damascus on July 28, going to Haifa, where he remained until Aug. 4, when he left for Europe.

The suppression of the Nationalists at Damascus did not immediately bring peace to the country, as the French were unable adequately to control the Hauran, and on Aug. 20 Bedouin raiders stopped a train at Khirbet el Ghazali on the Hejaz railway and murdered the Syrian prime minister 'Ala ed Din er Rubi, Ata el Ayyubi, the Minister of the Interior, and 'Abdurrahman Yusuf, President of the Council of State, for some time afterwards railway communication was hazardous in that area, and trains were generally protected by a guard of soldiers in armoured trucks at either end.

On Sept. 1 1920 Beirut became an autonomous district of the Greater Lebanon (*Grand Liban*), which was enlarged from its former extent under the Turks so as to embrace all Biqa' or the Coelestria composed of the Turkish kazas of Hasbeya, Rasheya, Biqa' and Baulbek (which, originally allotted to "O.E.T.A. West," were left to the administration of O.E.T.A. East by Gen. Allenby as having been largely liberated by Arab troops), and the coast territories between Palestine and the Nahr 'Akkar; and next day the former Turkish sanjak of Latakia and the northern parts of that of Tripoli were formed into a new administrative area of Alawiya (*Territoire des Alaouites*). In the N. the Turkish

sanjaks of Alexandretta, Deir ez Zor and Aleppo, were united (Sept. 1 1920) to form the "Government of Aleppo," which thus extended to the Khaur, beyond which the country was under the administration of the French officer commanding in the *Confins Militaires*; and by the end of the year the caravan route over the Beilan Pass above Alexandretta was so far cleared of Turkish raiders and Arab marauders that civilian traffic began to be resumed. In the S. however the Hauran was still disturbed, and in March 1921 a party of Arab raiders blew up bridges on the Hejaz railway over the Yarmuk and to the N. of Dera, while the Syrian Nationalists were reported to be active in that sector of the British sphere beyond the Jordan which still formed part of the Emir Faisal's dominions but was not in any way subject to British authority. In April however this danger was abated, as the Emir's elder brother, the Emir Abdalla, arrived in Amman and restored order throughout the area of the ancient kingdom of Kerak in cooperation with the British.

Frontiers—On Dec. 23 1920 the frontiers towards Mesopotamia and Palestine were fixed in such a way as to retain the whole of the Litani-Leontes watershed with Quneitira in French mandated territory, and providing for the joint Anglo-French use of the railway between Semakh and Nasib, although the line itself remains in French territory. On the side of Arabia the frontier runs from Nasib to Imtar and thence in a straight line to Abu Kemal on the Euphrates.

In March 1921 Gen. Gouraud, when in London for the Near Eastern Conference, took advantage of the presence of the representative of the Nationalist Turkish administration at Angora, Beki Sami Bey, to conclude an agreement, in virtue of which the French withdrew from the whole of Cilicia, and adopted as the northern frontier of their Syrian mandated territory a line running from Payas on the coast N. of Alexandretta to Choban Beg (Bey) on the Bagdad railway, and thence along the railway to Ni ibin, whence it runs to the Tigris and down that river as far as the frontier of Mesopotamia near Jeziret ibn Omar, thus restoring Kiliz, Aintab and Uria (Edessa) with an area of 22,500 sq. km. and an estimated pop. of some 640,000, to the Turks.

On March 4 1921 the formation of an autonomous Druse (Druz) State, comprising the Jebel ed Druz in the Hauran, to be under French supervision but independent of Damascus, was announced.

Area and Population—Thus the area comprised in Syria as defined by the boundary agreements of Dec. 1920 and March 1921 is divided into the Greater Lebanon (*Grand Liban*), Damascus, Jebel ed Druz, Alawiya, Aleppo and the military territory.

Although no exact census had been taken in Syria the following figures are supplied by the French administration—

I. Greater Lebanon (<i>Grand Liban</i>)			Area sq. km.	Pop.
	Sanjak	(Capital)		
(a)	South Lebanon	Sidon (Saida)	2,172	142,000
(b)	Beja'	Zahle	3,600	110,000
(c)	Mount Lebanon	Ba'albeka	3,900	180,000
(d)	North Lebanon	Shitoh	2,065	104,000
(e)	City of Tripoli		18	140,000
(f)	City of Beirut		—	—
Total			10,855	726,000
II. Alawiya (<i>Territoire des Alawites</i>)				
(a)	Sanjak of Latakia—composed of the kazas of Jebele, Sahyun, Baniyas (Vulena), Omrane or Masyaf and the municipal area of Latakia.			
(b)	Sanjak of Tartus—composed of the kazas of Tartus (Lortosi) Safita, Qul'at el Huri.			
Total area 6,200 sq. km. with a pop. of perhaps 400,000				
III. Government of Aleppo.				
(a)	Sanjak of Alexandretta, area 5,000 sq. km. divided into the kazas of Alexandretta pop. 26,000, Beilan pop. 20,200, Antioch pop. 126,900, and Hauran pop. 36,700, or 209,800 inhabitants for the sanjak.			
(b)	Sanjak of Deir ez Zor, area 30,000 sq. km. and a pop. of 174,000			
(c)	Sanjak of Aleppo.			
	City of Aleppo		—	144,006
	Kaza of Jebel Sima'an		4,694	25,130
	El Bab		2,437	27,752
	'Azaz		2,200	9,957
	Membij		3,867	5,030
	Ma'aret en Nu'man		3,450	21,629
	Idlib		1,800	53,598
	Raqqqa		7,200	9,865
	Jisr esh Shughr		1,125	36,018
			26,773	332,985
Total for the whole Government			61,773	716,785

IV Government of Damascus:		Area sq. km.	Pop.
(a)	Sanjak of Damascus.		
	Kaza of Damascus	600	238,504
	Wadi el 'Ajam	800	16,732
	Duma	841	37,937
	Zebdani	180	14,155
	Quneitara	2,000	43,183
	Jerude	—	29,431
	Nebk }	12,000	22,221
		<hr/>	<hr/>
		16,421	402,163
(b)	Sanjak of Hauran:		
	Kaza of Hauran	3,500	29,760
	'Ezra	1,318	30,018
	Musmiye	3,972	14,718
	Bosra Shams	970	26,436
		<hr/>	<hr/>
		9,760	100,932
(c)	Sanjak of Homs:		
	Kaza of Homs	4,000	88,214
	Qarvatein	4,000	6,945
	Joh Jerra	2,000	4,159
	Palmyra (<i>Tadmur</i>)	10,000	5,340
		<hr/>	<hr/>
		20,000	104,658
(d)	Sanjak of Hama:		
	Kaza of Hama	1,000	77,205
	Seleniye	2,500	20,864
	Hama	815	—
		<hr/>	<hr/>
		5,215	98,069
Total for whole Government		51,396	705,822
Thus the whole of Syria contains —			
	Greater Lebanon	10,855	726,000
	Alawiya	6,200	400,000
	Aleppo	61,773	716,785
	Damascus	51,396	705,822
	Jebel ed Druz }	—	—
	Military Territories	25,700	154,500
		<hr/>	<hr/>
		155,924	2,703,107

The precise boundaries of the state of the Jebel ed Druz had not yet been settled in 1921, but it was to be detached from the sanjak of the Hauran then in the Government of Damascus.

Administrative Divisions—Of these various administrative areas the Greater Lebanon is under a French Governor who appoints Lebanese officials to take charge of the seven departments of Interior, with *Gendarmerie* and Police; Finance, Justice and Pious Foundations, Public Works, Posts and Telegraphs, Education and Fine Arts, Agriculture, Trade and Industry, and Public Health. Each of these officials is assisted by a French adviser. The sanjaks are administered by Lebanese *mutesarrifs* with French advisers, assisted by local administrative commission. Pending a census of the population and a subsequent election a provisional administrative commission of 15 Lebanese members had been nominated. Its functions and powers are analogous to those of the old Administrative Council under the Organic statute of the Lebanon in 1863.

In Damascus the administration is directed by a Council of State composed of Ministers each assisted by a French adviser.

In Aleppo there is an Arab Governor who appoints native officials to take charge of the departments of Finance, Justice and Pious Foundations, Public Works, Posts and Telegraphs, Economic Services, and *Gendarmerie* and Militia. The Governor is assisted by a council and an administrative commission. The former is composed of the heads of the five departments, of heads of religious communities, of two members from each of the three sanjaks and of the mayors of Aleppo, Antioch and Alexandretta. The administration is supervised by a French Resident appointed by the High Commissioner, and French advisers assist the heads of departments and the *mutesarrifs* of sanjaks.

In Alawiya a French Administrator with French heads of the four departments of Finance; Public Works, Posts and Telegraphs; Public Health, and Justice and Pious Foundations, controls the administration. There is an administrative commission composed of seven Alawiye (or Nusairiye), two Christians, two Sunni Moslems and one Isma'iliye ("Assassin"). Each sanjak has a French Deputy Administrator with a native *mutesarrif* as his subordinate.

In virtue of the treaty of March 4 1921 between Gen. Gouraud and the religious and political chiefs of the Druses the State of the Jebel ed Druz in the Hauran is administered by a Druse governor elected by the population for four years, subject to the confirmation of the French High Commissioner. He is assisted by a council, elected for three years, which has one session every year during which the budget is voted, and by a permanent Administrative Commission. French advisers assist the higher Druse officials. The local *gendarmerie* and police are recruited by voluntary enlistment.

All these administrations, which are autonomous *inter se*, are subject to the general control of the French High Commissioner of Syria who

resides at Beirut, going into summer quarters at Aley in the Lebanon.

Currency—On May 1 1920 the standard currency of the pound Syrian (£S) was introduced to supersede the pound Egyptian (£E), which had been the official currency under the British occupation, and the now obsolete pound Turkish (£T). The £S is equivalent to the French *louis* of 20 frs., formerly well known in Syria, and is divided into 100 piastres of 20 French centimes each.

Railways—During the decade 1910-20 the railway construction in Syria was chiefly directed towards improving and linking up the lines serving the trade routes across, and little attention was paid to the development of a purely Syrian system for the development of the country. The only line which can be classed in this category is that between Tripoli and Homs, which was opened in June 1911, and even this was chiefly useful for importing the heavier material required for the construction of the Bagdad railway which was being built across the country in the north. During the World War it was taken up and its rails used in the extension of the Bagdad railway towards Nisibin, but after the French administration had been established the line was relaid and the railway was again opened for traffic in July 1921. In the same way the French Hauran railway between Damascus and Mzeirib was taken up and used in Palestine.

Of the Bagdad railway, destined to link the Syrian system with Haider Pasha, and perhaps with Europe and Mesopotamia, the Adana-Osmaniye (92 km.) and Dorak-Yenije (23 km.) sectors in Cilicia were opened on April 27 1911, the sector Bulgurlu-Ulu Kyshla (38 km.) in the Taurus was opened on July 7 1911, and that from Ulu Kyshla to Kara Punar (52 km.) in Dec. 1912. At the same time the Aleppo-Moslemiyeh (Muslimic) (15 km.), Moslemiyeh-Raju (77 km.), and Moslemiyeh-Jerablus (103 km.) fork was opened, and the branch from Toprak Kile (on the Osmaniye branch) to Alexandretta (60 km.) at the foot of the Beilan Pass was opened in Nov. 1913. This branch was cut in several places by H. M. S. "Doris" in Dec. 1914, but was reopened for traffic in 1921. During the war every effort was made to complete the great tunnels in the sectors Kara Punar-Dorak and Osmaniye Raju, and, after being used for narrow gauge traffic for some months they were opened for standard gauge use just before the Armistice, and the first through train from Haider Pasha reached Aleppo in Oct. 1918. Further E. the line was pushed forward to Nisibin—Jerablus-Tell el Abyadh (95 km.), Tell el Abyadh-Ras el 'Ain (87 km.), Ras el 'Ain-Nisibin (120 km.).

In Dec. 1913 in return for a French loan the Porte gave a concession for the extension of the French standard gauge railway then working between Aleppo and Kayak down through the Biqua' and Galilee to Ludd in Palestine, but nothing came of it, and no steps were taken to start the harbour works at Jaffa, Haifa, Tripoli and Alexandretta for which permission was granted at the same time.

During the war the railways of Syria were greatly stained to meet military requirements, damaged by hostile action, and inadequately kept up, rolling stock became worn out and many engines built for coal consumption were forced to use wood. As a result when the French took over the control of the Syrian railways in July 1920 they found them in need of wholesale reconstruction.

Agriculture—The chief Syrian industry is agriculture, and it is estimated by the French authorities that of 11,000,000 ac. available for cultivation in Aleppo, W. of the Euphrates, only about 1,500,000 were in 1921 under the plough. A still larger and even less developed area is known to be available for agriculture E. of the river. In the sanjaks of Hama and Homs and in the Biqua' the cultivable area is estimated at over 1,000,000 ac., while the Damascus oasis contains 1,500,000 ac. of good land.

The corn lands of the Hauran are reported to have produced 230,000 tons of wheat in 1919-20, of which 115,000 was exported to neighbouring districts. During the war the Hauran cultivators were generally able to sell their wheat to the Turks for gold, and it is estimated that they obtained £E2,000,000 in this way. Payments for animals and labour however were only in depreciated paper.

The tobacco district of Latakia in Alawiya used to produce some 1,000 tons of tobacco annually.

The production of silk in Syria, which fell during the war to less than one-tenth of its former volume, began to revive in 1920, and the export from Beirut nearly doubled on the 118 tons of silk and 82 tons of cocoons and allied materials exported in 1919.

Before the war it was estimated that there were some 5,000,000 sheep, 1,000,000 goats, 500,000 kine and 250,000 camels in Syria, but during the war it appears that the sheep and goats were reduced by at least 50%, the kine suffered more severely, and the camels, which were very wastefully used by the Turks for military purposes, were still further reduced in numbers, at least 40,000 having been lost in the Jordan valley alone in 1916-7.

Commerce—The trade of the port of Beirut since 1910, the last complete year of peace, may be summarized as follows:—

	Imports Tons	Exports Tons
1910	233,297	50,934
1911	216,162	48,078
1912	145,054	53,072
1913	193,844	49,248
1914	118,917	30,588
1919	64,547	18,547

Exports of Syrian produce from Beirut in 1911, the last normal year of peace, and in 1919, the first complete year since the Armistice, were as follows:—

	1911 Tons	1919 Tons
Wool	5,500	1,521
Hides	400	122
Olive Oil	233	90
Apricots	4,468	1,436
Wine	161	7
Gums	40	34

During the first quarter of 1920 466 tons of wool were exported from Beirut and 248 tons from Alexandretta, which had just been reopened for commercial traffic. In that period 67 tons of hides were exported from Beirut. For 1919 the value of imports was declared at the Customs as follows:—

	£E.
Jan.	59,597
Feb.	223,111
March	629,614
April	376,117
May	551,737
June	900,370
July	1,213,974
Aug.	534,332
Sept.	848,570
Oct.	781,366
Nov.	1,031,477
Dec.	895,248
	£E8,045,513

It must, however, be remembered that goods have to be declared at their local value, on which an 11% *ad valorem* duty is collected. During 1909 prices for imported goods were unreasonably high.

Archæology—Before the war extensive excavations had been started on the site of the ancient Carchemish, near Jerablus, under the direction of D. G. Hogarth, with the aid of T. E. Lawrence and C. L. Woolley. These operations, which had yielded highly satisfactory results after the interruption due to the war, during which these three archaeologists all distinguished themselves by their widely different services against the Turks, were resumed in Jan. 1920 under Mr. Woolley, and pursued in spite of the prevalent unrest and the actual hostilities which went on in the immediate neighbourhood. (II. P. C.)

SZÉLL, KOLOMAN (1845-1915), Hungarian statesman, was born on June 8 1845. He studied at Pest and Vienna, and in 1867 became deputy for the district of St. Gotthard. He very quickly won the reputation of being remarkably well informed on economic and financial questions. Széll was one of Deák's intimates, whose ward, the daughter of the Hungarian poet Vörösmarty, he had married. In 1875 he was Finance Minister in the Cabinet of Koloman Tisza, and as such imposed on himself the task of restoring the shattered credit of Hungary. In 1878 he concluded with Austria the first economic *Ausgleich*. At that time the single Austrian bank was changed, in conformity with this arrangement, into the dualistic Austro-Hungarian bank, and Széll consolidated the Hungarian Rentes, and nearly succeeded in balancing the State finances. As he feared that this balance would again be upset by the occupation of Bosnia and Herzegovina, he resigned from the Cabinet, incurring thereby the displeasure of the Crown. He still kept his seat in Parliament, and as deputy constantly criticized the financial policy of the Tisza Cabinet. At the beginning of the eighties Széll founded the Hungarian Mortgage Credit Bank, of which he was governor until the end of his life. He opened entirely new sources of credit for Hungarian agriculture. He declined repeated offers of the portfolio of Finance. When the Banffy Ministry suffered a serious crisis at the end of 1898 and was compelled to resign in Feb. 1899, Széll was entrusted with the formation of a new Cabinet. By means of the Pact of Feb. 23 1899 he restored parliamentary peace. On the basis of the so-called Széll formula the new *Ausgleich* with Austria until the year 1907 was concluded after long negotiations. The most important result of this was that Hungary attained the status of an independent customs area, but, under the arrangement for reciprocity, still maintained intact the existing conditions of the Customs Union with Austria. In 1901, under Széll's Ministry, the new elections resulted in a Liberal victory. A year later began the struggle for the reform of the national defence, and Széll introduced in 1902 the law for increasing the number of recruits, in exchange for which the Independent party wanted concessions to the principle

of nationality. The obstruction against the provision for defence lasted from the end of Jan. to April 4 1903, and resulted in the suspension of the constitution ("Ex lex" condition). Széll sought to wear down the opposition by delay. As part of the majority would not agree to this, he resigned on June 16 1903. When his successor, Count Stephen Tisza, on Nov. 18 1904 brought about a split in the Liberal party by forcing through Parliament new rules of procedure, Széll joined Count Andrassy in the secession from the party. Under the Coalition Cabinet of Wekerle, Széll was chosen president of the Constitutional party. He tried continually, but in vain, to bridge the opposition between Tisza and Andrassy. He died on Aug. 16 1915. (E. v. W.)

SZILAGYI, DESIDER (1840-1901), Hungarian statesman and jurist, was born at Nagyvarad (Grosswardein) on April 1 1840. He studied law at Budapest, Vienna, and in Germany, and early attracted attention by his articles on law and politics. As head of a section in the Hungarian Ministry of Justice he travelled on a commission from the Government to England to study there the conditions of the administration of justice, of which he had a knowledge then equalled by few. Brought up wholly in Liberal

ideas, Szilagyi took a conspicuous part in the codification work of the Ministry of Justice. Deputy in 1871, professor of public law and politics at Budapest University in 1874, he was in 1877 one of the leaders of the Opposition, which, however, he left in 1886. In 1887 he was returned to Parliament by Pozsony (Pressburg) as an independent member. He became Minister of Justice in 1889. From this time to 1894 he directed his efforts principally towards a radical reform of the whole administration of the courts. In 1894 he took a conspicuous part in ecclesiastical legislation, with which his name is permanently connected. Article XXXI. of the Law of Civil Marriage, and articles XXXII. and XXXIII. on the religion of the children and on State registration, were the result of his active coöperation. After the appointment of Baron Banffy, the former president of the Hungarian House of Deputies, as prime minister, Szilagyi was elected president of the House on Jan. 21 1895, which office he retained until 1899. A man of extensive knowledge, spotless character and wide vision, and a brilliant orator, he was one of the most considerable of the Hungarian statesmen of his day. He died on July 3 1901.

See *Szilagyi's Speeches* (4 vols., in Hungarian, Ed. Fayer).

(E. v. W.)

Even in 1921 there was a great need for more British floating docks of the largest description. This was more especially apparent on the Clyde, where there was no dock, either floating or graving, which could take capital ships.

The German ships were not handicapped in this way, and most of their later capital ships had widths of between 90 and 100 ft., which enabled them to carry more armour, and as far as it is possible to judge, they stood a good deal of battering without showing any lack of stability, while they proved to be good gun platforms, at any rate for work in the North Sea.

Immediately after war was declared great pressure was exercised to complete the ships then building for the British navy, and to order such other vessels as could be designed and finished in the shortest possible time. The view held in the early days that the war would only last a year necessarily coloured all that was done in the way of naval design and construction. Generally speaking, therefore, the construction of new battleships was ruled out. With the acquisition of the "Agincourt," "Erin" and "Canada," which were building in England for foreign Governments in private yards, and in view of the certain early completion of the remaining two vessels of the "Iron Duke" class, shortly to be followed by the vessels of the "Queen Elizabeth" class, Great Britain had a great preponderance of heavier capital ships, or Dreadnoughts, over the enemy; and as this class of ship takes longer to design and construct than any other, it was obviously a prudent course to concentrate on such types as were specially needed and could be built more quickly.

It should also be remembered that the menace of the submarine, which was from the first beginning to loom as a vital factor in the war, pointed in the direction of large numbers of patrol boats, torpedo-boat destroyers, and smaller types of vessels to deal with this menace. No time, therefore, was lost in placing orders for additional British destroyers, submarines, light cruisers, sloops, mine-sweepers, patrol boats, etc.; and it very soon became clear that the Royal dockyards and the regular warship-building contractors would not be able to cope with the mass of new construction that was required. Accordingly, orders for many of the last-named classes were placed with builders who had hitherto only been accustomed to mercantile work. With the arrangements that were made, however, for superintending and overseeing the work by the Admiralty, with the assistance of the registration societies—Lloyd's and the British Corporation—

very little difficulty was experienced in getting the work satisfactorily carried out by the firms new to this class of shipbuilding, and success attended the arrangements made.

Table II. gives the number and tonnage of vessels added to the British navy during the war. The total number (including other classes besides those in the table) was 1,513, of approximately 2,356,000 tons displacement.

TABLE II.—British Warships Completed and Lost Between Aug. 4 1914 and Nov. 11 1918.

	Completions		Losses	
	No.	Approx. Displacement	No.	Approx. Displacement
Battleships	15	395,000	13	201,000
Battle cruisers	3	81,500	3	63,000
Cruisers	3	56,500	13	158,500
Light cruisers	36	143,000	12	46,000
Monitors	40	126,000	6	14,000
Aircraft-carriers	8	67,500	3	27,500
Flotilla leaders	28	45,500	3	5,000
Torpedo-boat destroyers	255	273,000	64	52,000
Submarines	146	151,500	54	43,500
P. and P. C. boats	63	40,000	2	1,000
Sloops	124	155,500	18	22,500
Paddle mine-sweepers	34	27,500		
Twin screw mine-sweepers	55	43,000		
Patrol gunboats	30	27,000		
Oilers and petrol carriers	67	436,000		
Whalers, trawlers and drifters	382	173,500		

Battleships.—To take ships added to the British navy during the war in the proper order, it is necessary to begin with battleships of the "Iron Duke" class. The particulars of Dreadnoughts built after the "Hercules" are given in Table III.

The "Iron Duke" class (see fig. 1), of which there were four, followed the "King George V." class, both in sequence of time and in general characteristics. The same main armament, similarly arranged, with the five turrets all on the centre line of the ship, was adhered to, the chief difference in the "Iron Dukes" being that instead of the 4-in. guns forming the secondary armament, a battery of 12 6-in. guns protected by 6-in. armour was finally decided upon. The protection also was somewhat increased over that of the "King George V.," involving an increase in dimensions over any previous British battleships. Two of the class were laid down in Jan. 1912 and two in May, the four vessels being completed in March, June, Oct. and Nov. 1914, so that two were ready just

TABLE III.—Particulars of British Battleships.

Vessel	Date of Launch	Length between perpendiculars; (length over all)	Breadth	Mean Draught	Load Displacement: Tons	Speed: Knots	Horse Power	Armament	Thick-est side of Armour
"Orion"	1910								
"Thunderer"	1911	545 ft. (581 ft.)	88 ft. 6 in.	27 ft. 6 in.	22,500	21	27,000	10—13.5-in. 16—4-in. 3—21-in. T. T.	12 in.
"Conqueror"	1911								
"Monarch"	1911								
"King George V."	1911								
"Centurion"	1911	555 ft. (597 ft. 6 in.)	89 ft.	27 ft. 6 in.	23,000	21	27,000	10—13.5-in. 16—4-in. 3—21-in. T. T.	12 in.
"Ajax"	1912								
"Audacious"	1912								
"Iron Duke"	1912								
"Marlborough"	1912	580 ft. (622 ft. 9 in.)	90 ft.	28 ft.	25,000	21	29,000	10—13.5-in. 12—6-in. 4—21-in. T. T.	12 in.

"Canada"	1913	625 ft. (661 ft.)	92 ft.	28 ft. 6 in.	28,000	22½	37,000	10—14-in. 16—6-in. 4—21-in. T. T.	9 in.

before, and two shortly after, the declaration of war. Four torpedo-tubes were carried in lieu of three in the previous ships, and after the battle of Jutland a considerable amount of additional protection was added over the magazines—a course which was practically adopted in all British ships at that time as a precautionary measure. Only in one case was any portion of a shell found to have penetrated below the protective deck; but with the ever-increasing range at which actions were fought, and the increasing penetration of improved shell, the danger of the decks being inadequate had to be considered. Special interest is attached to this class, as the "Iron Duke" was the fleet flagship during the whole time of Adml. Jellicoe's appointment as commander-in-chief, and she was in action at Jutland with her sister ships.

FIG. 1.

The "Marlborough," it should be specially noted, was the only British battleship of the post-"Dreadnought" type struck by a torpedo during the whole war, and the value of the longitudinal protective bulkhead and of the subdivision and arrangements adopted was clearly shown, as the ship was able to remain in the line, no vital damage being done. She was afterwards safely docked in the Tyne and repaired. This is specially interesting, as many of the older ships, some with centre-line bulkheads and with other arrangements not so good for dealing with under-water damage, were sunk in the Dardanelles and elsewhere by enemy torpedoes.

FIG. 2.

The next type to note is the "Queen Elizabeth" class of the 1912-3 programme (see figs. 2 and 3). Three of these vessels, after taking a little more than two years to build, were completed in Jan., March and Oct. 1915. The other two were completed in Feb. 1916. A very considerable departure was made in the "Queen Elizabeth" from any previous "Dreadnoughts," the 15-in. gun taking the place of the 13.5-in., and the designed speed being increased by 4 knots over previous "Dreadnoughts," whilst the secondary armament was similar to that of the "Iron Dukes," consisting of 6-in. guns. Their very great increase of speed involved more than doubling the H.P. of the "Iron Duke" to give the 25 knots desired, and the great increase in the weight of the 15-in. guns and mountings over the 13.5-in. meant accepting only four turrets with eight 15-in. guns, as against five turrets with 10 13.5-in. guns in the previous ships, and even so the armament was considerably heavier. The further great departure from previous practice in battleships was the adoption of oil only as the fuel. This necessitated special arrangements of the oil bunkers, many of which were 30 ft. in height, and required special construction to withstand the head of oil. The armour and protection were fully maintained as compared with previous ships, but all these additions involved increasing the displacement to 27,500 tons.

In the battle of Jutland the Fifth Battle Squadron, consisting of four vessels of this class, were heavily engaged for several hours, and although they inflicted and sustained heavy punishment, especially in the case of "Warspite," all the vessels gave a splendid account of themselves and were not seriously damaged or put out of action. After the battle of Jutland additional protection was added to the magazines. The oil fuel proved a complete success in

the stress of war conditions, it being found easier to keep up a high sustained speed, with the smaller complement carried.

It should be noted that Sir Philip Watts was responsible as Director of Naval Construction for the design of the "Iron Duke" and "Queen Elizabeth" classes, thus completing a series of 27 battleships of the "Dreadnought" type designed and built during his tenure of office at the Admiralty—in addition to the large number of battle cruisers, light cruisers, destroyers and other vessels built during that period—truly a great record.

Following the "Queen Elizabeths" came the "Royal Sovereign" class of the 1913-4 programme (see figs. 4 and 5). These were the first capital ships built by the Admiralty to Sir Eustace d'Eyncourt's designs, he having succeeded Sir P. Watts in Aug. 1912. These vessels were to have the same armament as the "Queen Elizabeths," but as there was some question about the supply of oil fuel when the design was discussed, it was decided to revert to coal, and also to accept the slower speed of 21 knots, which would make them more homogeneous with other "Dreadnoughts." Subsequently, when the vessels were in process of construction and the great advantages of the use of oil fuel with other types of warships became apparent, it was decided to change from coal to oil, so enabling increased power, giving a speed of about 23 knots, to be obtained. When fully laden with about 4,000 tons of oil, the "Revenge" attained 22 knots, which was equal to about 23 knots in the designed load condition. A somewhat different disposition of deck and side armour was also adopted by which the thick protective deck at the

FIG. 4.

centre of the ship was brought up to the level of the main deck; this portion of the protective deck being thus well above the level of the deep load line, and giving more protected freeboard in the damaged condition than on any of our earlier battleships. This was an important feature, as a somewhat reduced metacentric height was decided upon for these ships with a view to making them steadier gun-platforms than some of the ships with more initial stability. The vessels were provided with good under-water protection, which was later reinforced by adding outside bulge protection. This was done to "Ramilles" before her launch and to the other vessels of the class after they had been in commission some time. The addition of "bulges" was suggested first by Sir E. d'Eyncourt originally for the "Edgar" class, for which this form of protection was added in 1914 after experiments had been made. The results proved the efficiency of the bulges.

The three battleships taken over by Great Britain from foreign Governments were of different types. H.M.S. "Agincourt" (see fig. 6) was commenced in Sept. 1911 for the Brazilian Government, from designs got out under Mr. Perrett at Elswick, but modified by Sir E. d'Eyncourt in Rio Janeiro, where he was then representing the Armstrong firm, before his appointment at the Admiralty. The Brazilian authorities, after much discussion, decided upon 14 12-in. guns, twin-mounted in seven turrets. This involved a ship with a length of 632 ft. between perpendiculars and 670 ft. over all. The main armour was somewhat lighter than that of British "Dreadnoughts" and in other respects, such as fuelling facilities, the ship hardly came up to the British standard. However, she was well reported on, and the 14 big guns were liked by the gunnery officers, who preferred a large number of guns for their salvoes. Certain alterations had to be made to fit her for the British service, but in the main she was left as designed.

It should be mentioned that in 1914 the "Agincourt" was transferred by Brazil to Turkey and she was on the point of leaving the Tyne for Constantinople when, on the declaration of war, she was taken over by the British Government.

The design of the "Erin" was settled by three firms, Armstrong's, Vickers and John Brown, in consultation with the Turkish authorities, for whom the vessel was built, being commenced in 1911. In general characteristics she more nearly followed the "King George V." class than any other British ship, except that the secondary armament consisted of 6-in. guns, as in the "Iron Duke" class. This vessel also was taken over by the British Government in Aug. 1914, and certain modifications made to fit her for the British service. In respect of quantity of fuel carried, the "Erin" was below the standard adopted for vessels designed for the British navy.

The third ship taken over from a foreign Government was ordered and commenced in 1911 at Elswick from designs prepared at Elswick by Mr. Perrett for the Chilean Government. There were two ships of the class, the "Almirante Latorre" (which became H.M.S. "Canada"), and the sister ship the "Almirante Cochrane" (now H.M.S. "Eagle"). The "Canada" had 10 14-in. guns, twin-mounted, in the centre line, and was originally designed to have 22 4.7-in. as the secondary battery, but this was subsequently altered to 16 6-in. guns. The protection again was somewhat lighter than that of the British "Dreadnoughts," but the speed was rather higher, viz. 22½ knots, and as a matter of fact this speed was considerably exceeded on trial. The ship was taken over by the British Admiralty in Sept. 1914, and completed, after certain necessary modifications, a year later. Her fuel consisted of coal, with the addition of a certain amount of oil, as in most British battleships. In 1920 the "Canada" was returned to the Chilean Government under her original name.

The sister ship, "Almirante Cochrane," remained in an uncompleted condition on the stocks at Elswick till early in 1918, when she was taken over by the British Government and rearranged as an aircraft-carrying ship. She was renamed H.M.S. "Eagle," and as a compliment to the U.S. navy, she was, at the request of the Admiralty, launched by Mrs. Page, the wife of the then American Ambassador to Great Britain.

Battle Cruisers.—As regards the British battle cruisers later than the "Princess Royal," particulars are given in Table IV.

The "Tiger" was included in the 1911-2 programme and followed on the "Queen Mary," the general features of the two ships being much alike, the chief differences being that the secondary armament of "Tiger" is 12 6-in. guns in lieu of 16 4-in. in "Queen Mary," and "Tiger" has two submerged torpedo-rooms, whereas "Queen Mary" had only one.

The "Tiger" was laid down at Clydebank on June 12 1912, and completed in Oct. 1914. In common with so many ships completed during the war, the early commissioning and joining of the fleet was so imperative that no exhaustive trials in deep water were carried out, but the runs made on the Polperro course showed that the designed power of 108,000 S.H.P. could be obtained with little difficulty, corresponding to a speed of 30 knots. In the early stages of the design the oil-fuel capacity was very largely increased from 1,000 tons originally intended to a maximum oil stowage of 3,480 tons, in addition to the 3,320 tons of coal.

FIG. 7.

At the commencement of the war two additional battleships of slightly modified "Royal Sovereign" type, viz. the "Renown" and "Repulse" (see figs. 7 and 8), had been laid down, but in view of the long time it would take to complete these ships, the construction was not pressed forward. Immediately after the battle of the Falkland Is., in which the British battle cruisers "Invincible" and "Inflexible," in company with other smaller cruisers, annihilated Von Spee's fleet, the value of the battle cruiser type became very apparent, and on the initiative of Lord Fisher, then First Sea Lord, it was decided to stop the construction of "Renown" and "Re-

pulse" as battleships and to alter the design completely into that of very fast battle cruisers.

Instructions to redesign these ships were given about Christmas 1914. The new design had to give a speed of 32 knots, with the largest number of big guns possible for such a vessel, and with protection similar to that of the "Invincible" class. A modified form of bulge was adopted in these ships to give additional under-water protection against torpedo attack. After the war further additions were made to the bulge protection and to the armour.

FIG. 9.

The general outline design was completed and approved in ten days, and 6 15-in. guns adopted as the main armament, the secondary armament consisting of 17 4-in. guns, of which 15 were mounted in five specially designed triple-gun mountings. It was necessary that the ships should be completed at the earliest possible date, and the "Tiger's" machinery was repeated with some additional boilers, with oil as the fuel, thus increasing the power to 120,000, which, with the extra length given to the ship, made it possible to obtain the desired speed of 32 knots.

Lord Fisher also insisted that the ships must be completed within 15 months—an abnormally short time for an entirely new design—this period of completion was not realized, although not greatly exceeded. By Jan. 21 1915 the two firms entrusted with the orders, viz. Messrs. John Brown and Fairfield, were supplied with sufficient information to enable them to proceed with the structure, and both keels were laid on Jan. 25, which was Lord Fisher's birthday. All the drawings and specifications were completed by April and the design finally approved in that month.

The arrangement of the whole ship, showing the protection, is given in fig. 7, the plating over the magazines having been considerably increased as a result of the Jutland fight.

"Repulse" was launched in Jan. 1916, less than a year from the laying down, and "Renown" was launched three months later.

"Repulse" went through her commissioning trials early in Aug., and "Renown" followed one month later and was completed in September. The speed of "Repulse" on trial was over 31½ knots in the deep condition, and the "Renown" obtained 32.6 knots mean speed in the normal condition.

The construction of these vessels in a little over one and a half years from the first order to get out the design constitutes a record in design and construction of two such important vessels, and reflected great credit, not only upon the Royal Corps of Naval Constructors, but also upon the contractors and all concerned in the construction and completion of the vessels. In fact, the Admiralty conveyed their appreciation of this to Sir E. d'Eyncourt, the Director of Naval Construction, in a letter dated Sept. 1916.

The battle cruiser H.M.S. "Hood" (see figs. 9 and 10), the latest addition up to 1921 to the capital ships of the British Fleet, was designed early in 1916, and had only just been ordered from Messrs. J. Brown & Co. when the battle of Jutland took place. This great event naturally led to a revision of the design and in view of the damage which was then done to British battle cruisers and also to

TABLE IV.—Particulars of British Battle Cruisers.

Vessel	Date of Launch	Length between perpendiculars; (length over all)	Breadth	Mean Draught	Load displacement: Tons	Speed: Knots	Horse Power	Armament	Thickest side Armour
"Lion"	1910	660 ft.	88 ft. 6 in.	28 ft.	26,350	28	70,000	8—13.5-in. 16—4-in.	9 in.
"Princess Royal"	1911	(700 ft.)						2—21-in. T.T.	
"Queen Mary"	1912	600 ft. (703 ft. 6 in.)	89 ft.	28 ft.	27,000	28	75,000	8—13.5-in. 16—4-in. 2—21-in. S.T.	9 in.
"Tiger"	1913	660 ft. (704 ft.)	90 ft. 6 in.	28 ft. 6 in.	28,500	30	108,000	8—13.5-in. 12—6-in. 4—21-in. T.T.	9 in.
"Renown"	1916	750 ft.	90 ft.	25 ft. 6 in.	26,500	32	120,000	6—15-in. 17—4-in.	6 in.
"Repulse"	1916	(794 ft.)						2—21-in. T.T.	
"Hood"	1918	810 ft. (860 ft.)	104 ft.	28 ft. 6 in.	41,200	32	144,000	8—15-in. 12—5.5-in. 6—21-in. T.T.	12 in.

the German ships of similar type, it was deemed advisable to increase the armour protection, if possible. As the result of very extensive investigations, it was found possible, by accepting a deeper draught and a slightly reduced speed, to add very considerably to the protection of the vessel as already designed, without otherwise seriously affecting the design of the ship as a whole. The alterations were of a very radical character, the armour belt being increased from 8 to 12 in. and the barbettes from 9 to 12 in.; and certain increases were also made in the deck protection. At the same time the eight 15-in. gun mountings had their design modified to admit of an elevation of 30 degrees, and certain other modifications were made, both in the torpedo armament and also in the arrangements for preventing the flash penetrating to the magazines—a form of protection which was elaborated for all British ships at this time. All these increases involved an additional weight of nearly 5,000 tons, the legend displacement of the "Hood" becoming finally 41,200 tons when carrying 1,200 tons of fuel; the ship then having a draught of 28½ ft., and a draught of 31½ ft. with full fuel load, viz. 4,000 tons.

The original length and beam of the ship were maintained as before. Some extra plating had to be provided on the decks for strength purposes, but the under-water protection against torpedoes was retained as in the original design. With the modifications made, the "Hood" when completed was by far the most up-to-date capital ship in existence.

The changes in the design and other circumstances militated against the quick construction of the ship, and it was about four years from the approval of the original design in April 1916 to the time of her completion, this being about double the time taken to build recent British capital ships, and nearly three times that taken to build the "Repulse" and "Renown." The modifications were, however, quite justified by the circumstances, and they made the ship a much more powerfully protected one, whilst increasing her displacement, and consequently the weight of material to be worked, to about 50% more than that of "Repulse" and "Renown."

The main machinery of the "Hood," consisting of geared turbines to develop 144,000 H.P., has the largest power which has ever been put through gearing, namely, 36,000 H.P. on each of the four shafts. The machinery is placed in three engine-rooms, of which the forward one contains two independent sets for the outer shafts; the middle and after engine-rooms contain one independent set for each of the inner shafts. This power, which was designed to give 32 knots for the earlier design of 36,300 tons displacement, was expected to give at least 31 knots in deep water with 210 revolutions of the propellers, at a displacement of 41,200 tons for the "Hood" as built. The 24 boilers represented the small-tube type with forced draught, arranged in four boiler-rooms. Such boilers were first adopted for large vessels in the "Courageous" class. Oil is the only fuel used in "Hood." On trials on the measured mile the "Hood" obtained a speed of 32.07 knots with 151,000 S.H.P. at 42,200 tons displacement, and 31.9 knots with 150,000 S.H.P. at 44,600 tons displacement.

It will be seen from the plan (fig. 9) that the main armament of eight 15-in. guns was mounted, as in recent British battleships of the "Queen Elizabeth" and "Royal Sovereign" classes, in four turrets, all on the centre line, with very large arcs of training, the forward ones training to 60° abaft the beam, and the after ones to 50° before the beam. The anti-torpedo-boat destroyer armament consists of twelve 5½-in. guns arranged on the fore-castle deck and shelter deck. There are also four 4-in. anti-aircraft guns on the shelter deck aft. There are two 21-in. submerged torpedo tubes, each in a separate compartment forward, and four 21-in. above-water torpedo tubes between the upper and fore-castle decks; these above-water tubes being a further addition since the original design was made. The distribution of armour is also shown. The 12-in. belt had a length of 562 ft. and a depth of 9 ft. 6 inches. Above the main belt was a strake of 7-in. armour to the height of the upper deck, and above that again there was 5-in. armour between the upper and fore-castle decks. The side armour all sloped outward from below, the shell being thus unable to hit the armour normally, so that the virtual thicknesses were somewhat greater. There was thick plating behind all the armour, varying from 2 in. over the greater portion to 1½ in. and 1 in. elsewhere. The torpedo protection consisted of the bulge arrangement, with an outer compartment of air and an inner one specially strengthened with the necessary separating bulkheads, etc. This protection extended throughout the whole length of the machinery spaces and magazines, and it has been proved that it renders the ship as safe against attack from torpedoes under water as she is against gun attack above water. The oil fuel tanks are arranged along the sides, thus giving additional protection. The "Hood" was successfully launched in Aug. 1918 at Clydebank, the ceremony being performed by Lady Hood, widow of Adml. Hood, who lost his life whilst gallantly leading into action the Third Battle-Cruiser Squadron at Jutland. The launching weight was about 22,000 tons. As the other three ships of the class which were commenced had none of them reached the launching stage at the time of the Armistice, it was subsequently decided not to proceed with them, in view of the international conditions, and the "Howe," "Rodney" and "Anson" were accordingly scrapped.

As regards the general design of the ship, the "Hood" may be

cited as an example of what can be achieved by going to a large size. Her design embodies the armament and armour protection of a first-class battleship, including also good under-water protection against torpedoes, and at the same time gives the speed of the fastest battle cruisers. This involved great length and displacement. The under-water bulge protection, which has entirely superseded the provision of torpedo netting, is additional to anything provided in pre-war "Dreadnoughts."

In connexion with the size of the "Hood" and general considerations of design, it is interesting to note the chief characteristics of the "Queen Elizabeth" and "Renown." The "Queen Elizabeth" is a well-armoured ship of about 28,000 tons, with eight 15-in. guns and speed of 25 knots, while "Renown," of slightly less displacement, viz. 27,000 tons, though of greater length, is a vessel with 7 knots more speed than "Queen Elizabeth," but with only six 15-in. guns against eight, and approximately about half the armour protection provided in the "Queen Elizabeth." The "Hood" has the same armament, viz. eight 15-in. guns, as the "Queen Elizabeth," armour protection fully equal to and, in fact, rather heavier in the aggregate than that of the "Queen Elizabeth," 7 knots more speed than the "Queen Elizabeth," which makes the speed about equal to that of "Renown," and in addition complete protection against torpedo attack.

FIG. 11.

Large Light Cruisers.—Early in 1915, as sanction was not given by the British Government for building more capital ships taking two years or longer to complete, while additional light cruisers had been already approved of, it was decided to build "Courageous" and "Glorious" (figs. 11 and 12) on the lines of very large light cruisers mounting a few guns of heaviest calibre, so as to be able to annihilate any enemy light cruisers or raiders. They were to have light protection, similar to British light cruisers, and a speed of not less than 32 knots, the draught being restricted to about 22 ft., or about 5 ft. less than any existing battleships or battle cruiser carrying such heavy guns, the main armament of four 15-in. guns in two turrets, one forward and one aft, making them a match for any raider or light cruiser that might be encountered. At this time it should also be remembered that the armaments of ships, especially as regards heavy guns, had to be regulated by the guns and gun mountings which would be available or could be manufactured in a short time, and this condition applied to the 15-in. mountings which were adopted for these ships. The secondary armament consisted of eighteen 4-in. guns in six triple mountings, similar to the triple mountings of the "Renown" and "Repulse." The side armour consisted of 2-in. protective plating added to the 1-in. shell plating, and a thin protective deck was worked all fore and aft, but this was considerably thickened over the magazines after Jutland. A modified "bulge" was arranged for, as in "Renown" and "Repulse."

The machinery adopted for these ships was of the type fitted in the light cruiser "Champion." It consisted of a 4-shaft arrangement of geared turbines, the power being transmitted to the propeller shafts by double helical gearing. The eighteen boilers of Yarrow small-tube type were also similar to those of the light cruisers, and with all-oil firing a power of 90,000 S.H.P. at about 340 revolutions of propellers was aimed at. Such trials as it was possible to make showed that 32 knots could easily be obtained at the designed displacement, and on service this was actually exceeded.

It was intended that these vessels should be built in a year, or as near that as possible, but this was not realized, and the ships were both commissioned in Oct. 1916.

The "Furious" (see fig. 13), was similar to, but a modification of, the "Courageous" and "Glorious," having about the same length and the same machinery, but the form of midship section was somewhat different, having a more pronounced bulge and a simpler form of main framing and structure of the hull. The armament also was different; each turret, instead of having two 15-in. guns, was arranged to carry one big gun of 18-in. bore.

Early in the spring of 1917 the necessity for having fast aeroplane-carriers became very obvious, and it was approved to fit "Furious" for this purpose. This entailed the removal of the fore turret and making other considerable alterations. A large hangar was built on the fore-castle deck, and a flying-off platform 160 ft. long was arranged on the roof of the hangar, which was designed to house about 10 machines. Later it was decided to remove the after-turret as well, and a flying-on deck 300 ft. long, extending from the funnel

was constructed. The secondary armament, which had consisted originally of 11 5½-in. guns, was retained, with the exception of one gun; the remaining 10 guns being rearranged. Four sets of the 21-in. torpedo tubes were fitted on the upper deck aft, and a pair each side on the upper deck forward.

After these alterations were completed, the ship was tried and commissioned in July 1917, a speed of 31½ knots being obtained at 94,000 S.H.P. at 330 revolutions. From the speed point of view the great advantage of size and length is clearly shown in these ships compared to T.B.D.s, since with about three times the H.P. a destroyer it is possible to drive a ship of nearly 20 times the displacement at the same speed. This in smooth water; in anything but head sea the T.B.D.s are left behind altogether by the great ships (see Table V.).

Light Cruisers.—Following upon the previous light cruisers of the "C" class, a very important departure was made in the light cruiser design in the programme 1912-3, when the "Arethusa" (see fig. 14) was designed by Sir Philip Watts. The importance attached to speed was specially brought out in this design, and it was decided to install very powerful machinery of 40,000 S.H.P. this could only be achieved by adopting engines and boilers closely approximating to those hitherto used only for destroyers.

In conjunction with high speed a good armament was provided, consisting of two 6-in. and six 4-in. guns, though in the original design the armament consisted entirely of 4-in. guns. The ship's speed up to the level of the upper deck were protected by a high side plating varying from 2-in. to 1½-in. and 1-in. in addition to 1-in. shell plating. This arrangement of plating also greatly added to the strength and stiffness of the ship. Further particulars of the class are given in Table V.

The "Arethusa" and other light cruisers were in the action off Iceland on Aug. 28 1914.

In the 1913-4 programme the "Calliope" class, slightly larger than the "Arethusa," but with the same power, were decided upon, the designs being made by Sir E. d'Eyncourt. After considerable discussion regarding the merits of mixed or homogeneous armament, it was decided to give these vessels two 6-in. guns, both on the centre line placed aft, and eight 4-in. guns. The section consisted, as in the previous design, of a belt with a total thickness of approximately 3 inches. Most of this class had practically the same machinery as the "Arethusa," but Parsons geared engines were installed in two of them, the "Calliope" having two shafts and the "Champion" two shafts. This was at the time a very important experiment, the putting of 20,000 H.P. through gearing being a very bold departure from anything which had been hitherto contemplated. The final results obtained with "Champion" were, however, excellent, and she obtained a speed of 31½ knots with 337 revolutions and about 41,000 S.H.P., this being slightly in excess of any of the other vessels of the class corresponding displacement.

The "C" class are the first ships, other than battleships, to have exposed guns on the middle line, a sort of spoon-shaped bulge being fitted to protect the crew of the lower from the blast of upper gun firing over them.

For the subsequent vessels of the "C" class reference should be made to the tables, which show a gradual growth in size and power; "Ceres" (fig. 14) finally having a length of 311 ft. and a beam of 43 ft. 6 in., and a normal displacement of 4,200 tons. These vessels carried five 6-in. guns, all on the centre line.

FIG. 15.

The next class were the "D's" (figs. 15 and 16), the general arrangement and protection of which followed that of the "Ceres," except that six 6-in. guns were carried on the centre line instead of five. The power was only slightly increased in these ships over the previous classes, but the revolutions were reduced to 275, all these ships having the twin-screw geared arrangement, and although the displacement of the "D's" increased to 4,650 tons, the additional length and the reduction of revolutions enabled the speed of 30 knots of the whole class of light cruisers "C's" and "D's" to be maintained.

In addition to these light cruisers, which were all to Admiralty design, two vessels—the "Birkenhead" and "Chester"—built at Messrs. Cammell, Laird's for the Greek Government, were pur-

chased in 1915. These vessels were considerably heavier than the "C" class and more closely resembled the British "Chatham" class. They carried an armament of ten 5½-in. guns. The boilers were modified to burn only oil in the "Chester," instead of coal and oil as in the "Birkenhead," and the resulting increase in power to 31,000 gave the former a speed of 26½ knots.

Designs were prepared in 1915 of the "Raleigh" class (figs. 17 and 18), a considerably heavier type of light cruiser, more especially suited for ocean work in any part of the world. They were to have a speed of 30 knots and a large radius of action. Various armaments were considered, and it was finally decided to adopt an armament of seven 7.5-in. guns with twelve 3-in. (four being on high-angle mountings). Five of the big guns were placed on the centre line,

FIG. 17.

and the other two were on the broadsides amidships. The bow and stern guns were superposed, thus giving a fire of four guns, both ahead and astern, and six guns on either broadside. These ships were originally designed to burn oil and coal, but the coal-burning boilers were subsequently altered in three ships of the class to burn a larger amount of oil, the original power of 60,000 S.H.P. on a four-shaft geared turbine arrangement being thus considerably increased up to about 70,000 shaft horse power.

These vessels also differed from the light cruisers referred to above in having modified bulges as protection against under-water attack. The protective plating was similar to that of the other light cruisers. One of these ships, the "Cavendish," was altered into an aircraft-carrier, and renamed "Vindictive."

Monitors (see Table V.).—The first vessels of this type to be added (or reintroduced) to the British navy were the three ex-Brazilian river monitors built by Messrs. Vickers, Ltd., and taken over by the British Government in Aug. 1914, and renamed "Humber," "Mersey" and "Severn." The particulars of these vessels are given in the table, from which it will be seen that the armament consisted of medium-calibre guns, viz. 6-in. and 4.7-inches. These vessels, though designed for river service, did very good work in the war, both on the E.-African and Belgian coasts.

The need for vessels of the monitor type mounting heavy guns soon became apparent, and in Nov. 1914 it was decided to prepare designs of monitors of more substantial structure for sea-going service, but of light draught, with good protection and carrying some heavy guns, the light draught combining the advantages of being able to go close inshore and greatly reducing the risk of being struck by a torpedo.

The earliest design was that of the 14-in. gun monitors, four in number, which was commenced in 1914. Four twin-mounted 14-in. guns and mountings were available, and with the very simple form of structure adopted, these vessels were designed and built in six months. They were quickly followed by the 12-in. monitors, which were of similar design but carried pairs of 12-in. guns, taken from older battleships. These vessels were also built in about six months. They all had a complete bulge of a form which was of simple construction, with an air space outboard and a water space between that and the ship proper.

Following on the 12-in. monitors, early in Jan. 1915 two more vessels were ordered, mounting a pair of 15-in. guns. For these ships, internal-combustion engines, which were well under way, but designed for another purpose, were installed. These vessels were named the "Marshal Ney" and "Marshal Soult."

In Sept. 1915 two improved 15-in. monitors were ordered and named the "Erebus" and "Terror" (figs. 19 and 20). These were of finer form, of more horse power and a speed of 14 knots.

Following the earlier 15-in. monitors, some much smaller vessels, each carrying a 9.2-in. gun, were designed, and others again which carried 6-in. guns. A good many of both large and small monitors went out to the Dardanelles in the early part of the war, and did very good work, and for a long time they seemed to bear a charmed life, as they enjoyed complete immunity from torpedo attack. Later, however, the "Erebus" and "Terror" were both torpedoed; the latter received three torpedoes, two hitting forward of the bulge with severe damage resulting; the third, which hit the bulge itself, did very little damage. The former ship was hit full amidships by a distance-controlled boat carrying a very heavy charge, but the bulge gave her complete protection and both ships were quickly repaired. It is interesting to note in this connexion that some of the old

British cruisers of the "Edgar" class, which had had bulges added to them early in the war, were torpedoed in the Mediterranean, but the bulge gave them complete protection. They were taken to port and repaired. In fact, no bulged ship struck by a torpedo was sunk.

On the heavier monitors it may be remarked that of all ships carrying heavy guns these vessels were probably more often in action off the Belgian coast and elsewhere than any of our heavy-gun ships, and they no doubt gave the enemy in occupation of that coast a very anxious time.

Destroyers and Flotilla Leaders (Table V.).—With regard to the development of British destroyers and flotilla leaders during the war reference may be made to the tables and plans (figs. 21, 22, 23 and 24). These vessels gradually increased in size and power, and war requirements continually added to the weights which they had to carry, including considerably more fuel, heavier armament both

of guns and torpedoes, depth charges, larger bridges, and other additions. In fact, some of the ships which before the war were 900-ton vessels, exceeded 1,000 tons towards the end. The introduction, however, of the geared turbine added enormously to the efficiency of the machinery and propellers.

During the war nearly 300 T.B.D.'s and flotilla leaders, which are simply a larger form of T.B.D. with improved accommodation, were added to the British fleet, and the whole class of these vessels was called upon to do continuous work often in heavy weather. They came through the ordeal with very few breakdowns of machinery or other parts of the ship, whilst the duties they were called upon to perform in combating the submarines, convoying, etc. were continuous and varied. Numbers of these vessels were built by firms who had never built a warship before, but the work turned out by them fully met the Admiralty requirements.

The flotilla leaders, with a deep load displacement of about 2,000 tons and an armament of five 4-in. or 4.7-in. guns, and with their very high speed, might well be described as fast scouts or third-class cruisers.

Patrol Boats (Table V. and fig. 25).—Patrol boats were specially designed to relieve the T.B.D.'s of some of their duties such as patrolling, submarine-hunting and escort work, for which high speed was not a necessity. They had to be as small as possible, consistent with keeping the sea in all weathers, with sufficient speed to run down submarines, besides having shallow draught and all top hamper kept low to prevent their being seen at a distance. Economy of fuel was also an important feature, and it was desirable to have them built of mild steel rather than high-tensile steel, in order to simplify the construction. Some were provided with a special hard steel ram, with which a considerable number of enemy submarines were sunk. The various features were combined in a vessel of something under 600 tons, with geared turbine engines of 3,800 H.P., giving a speed of over 22 knots, with 330 revolutions of the propellers. The boats had large rudder area and were cut up aft, so that they could turn very quickly upon the enemy—a most important feature for ramming purposes. They proved very valuable boats

FIG. 19.

on service and did a great deal of work against the submarines in all weathers. They were armed with only one 4-in. gun, mounted in a commanding position on the forward superstructure, one 2-pdr. and two 14-in. torpedo tubes, and later it was arranged to carry depth charges. Their cost was, of course, considerably less than that of a modern destroyer.

Some of these boats were afterwards disguised to look like small mercantile craft—a device which also proved quite successful.

Sloops and Mine-Sweepers.—On the outbreak of war it became clear that there would be a great demand for mine-sweeping vessels. A good many coasting and cross-channel steamers were taken up for this purpose, but more were required, and it was decided in Dec. 1914 to build twelve single screw ships (fig. 26) of simple design to this end. With the view of hastening construction, it was decided to adopt mercantile practice as far as possible in both hull and machinery. The vessels, although of very fine form, were built of simple construction and under Lloyd's survey. The boilers were of ordinary Scotch type, and single screw machinery was provided.

FIG. 21.

In the end nearly 100 of these vessels were built, and the armament, which at first was two 12-pdrs., was subsequently increased to two 4-in. or two 4.7-in. guns. A great many of these vessels were built in about six months from the order, and the first 36 averaged 25 weeks in building. They proved excellent sea boats, and were used not only for mine-sweeping, but also for submarine work and for convoying. At later stages some of these vessels were disguised as ordinary merchant ships. They were economical steamers, and were able to attain a full speed of 17 knots, with a H.P. of about 1,800 to 2,000 in the earlier, which was increased to 2,500 in the later vessels.

Several of the vessels were mined, but although the damage they sustained was very severe, they kept afloat and were repaired.

The Admiralty was asked to design and provide some vessels of this type for the French Government, and eight of these were designed by Sir E. d'Eyncourt and built for that purpose and armed

with somewhat heavier armament than our own ships. The French Government were very satisfied with the vessels.

In addition to this, at a later stage, for sweeping in shallow water, some paddle mine-sweepers were designed at the Admiralty. These were 15-knot boats, with draught just under 6 ft. 9 inches. They did good work, but were of course not such good sea boats as the sloops. As there was some danger of mines getting under the paddles, a further design of twin-screw mine-sweepers was got out. These were vessels of about 800 tons and about 16 knots speed.

Submarines (Table V. and figs. 27, 28 and 29).—During the war the design of submarines was enormously developed. A very large number of these vessels were added to the British Fleet. There were some twelve different types, some embodying very special requirements and all being improvements on their predecessors. The Admiralty produced the fastest internal-combustion engined submarine in "J" class, which attained a speed of over 19 knots. As a still higher speed was wanted for fleet work, the "K" boats were designed with a surface speed of 24 knots. To arrive at this it was necessary to go to steam, and special arrangements had to be made for shutting down watertight the funnels, etc. However, all these difficulties were overcome.

It is an interesting point about these vessels that, besides the steam turbines for full speed on the surface and the electric drive when under water, they were provided with a Diesel engine for use just before diving or immediately after breaking surface, in order to quicken diving or getting away after coming up.

Although the Germans had the advantage of more power per cylinder in their Diesel engines, Great Britain produced submarines, faster and more heavily armed than theirs.

M. 1. submarine was a monitor submarine armed with a 12-in. gun; she was an experimental boat, and proved quite successful.

"China Gunboats."—For use in Mesopotamia or for river work two classes of so-called "China gunboats" were designed by Messrs. Yarrow. The smaller of these vessels, 120 ft. long and of about 100 tons, were constructed in Great Britain in such a way that the parts could be sent out to Abadan, where they were assembled, and the vessels refitted and completed under the supervision of Admiralty officers. Some of the larger boats 230 ft. long and of 645 tons, were completed in England and went out to Mesopotamia, where all of them were of the greatest service in that campaign. Most useful work was also done by motor launches and many other types.

Other Auxiliary Craft and Aircraft Carriers.—The Admiralty was called upon to design many other auxiliary craft—notably some fast Fleet oilers which were able to carry 5,000 tons of oil and had a speed of 15 knots. There were also designed a great number of special smaller craft for all purposes, and a number of merchant ships were taken over and modified to meet diverse requirements.

The most important modifications were those made to vessels taken over and converted into aircraft-carriers, including "Campania," "Ark," "Royal," "Engadine," "Riviera," etc.; the "Furious" was also altered, and the "Cavendish" (now named "Vindictive") was converted into an aircraft-carrier. The "Argus" (fig. 30) was originally built as a passenger mail ship of 20 knots, and was taken over and converted into an aircraft-carrier with complete flush deck, the funnels being carried aft in long horizontal ducts, discharging the smoke astern. The "Eagle" was taken for conversion into a large aircraft-carrier with a somewhat different arrangement, with the funnels and all deck erections included on an "island" on one side of the deck. Aircraft-carrying ships are in fact gradually becoming more important for the Fleet.

Altogether during the four years more than 2,000,000 tons were added to the navy, at a cost between £250,000,000 and £300,000,000 sterling, exclusive of modifications to auxiliaries. Reference to the navy estimates shows that the aggregate sum spent during the four years before the war on new construction amounted to approximately £60,000,000. In fact, during the four years 1915-8, more tonnage was built for the British navy than during the previous 25 years.

II. NAVIES OF OTHER COUNTRIES

During the period 1910-20 foreign naval construction of all types generally followed the line of British designs, with one or two important exceptions which must not be overlooked.

The most important departure from the British practice was in respect of the number of guns mounted in the barbettes. Triple-gun mountings for the main armament have been adopted by several nations, viz. France, Italy, Austria, Russia and the United States, while in 1914 the French began the construction of quadruple-gun turrets, but neither these turrets nor the ships for which they were intended have been completed.

The British example in regard to the adoption of turbine machinery for propulsion of the first "Dreadnought" battleship and battle cruisers was not followed by the other nations at once. In some cases, for example, Japan and the United States, sister vessels were built, one having turbine engines and the other reciprocating engines. Finally, however, turbine engines were almost universally adopted, while the United States made a fur-

their advance by the adoption of the electric drive. The first American battleship in which this was installed was the "New Mexico," and it was arranged for all subsequent vessels to be propelled similarly.

In the adoption of oil only as the fuel the British again took the lead, and up to Aug. 1921 this had only been followed by the United States. The German authorities had considered that their sources of supply were not sufficiently reliable to justify their depending on oil alone.

On the whole, therefore, it may be said that the designs, apart from the above features, of foreign warships did not differ essentially from the British types, as can be seen from the notes and tables which follow.

Of the minor navies, many of which depended on British or other foreign builders for the design and construction of their warships, little need be said, as with the war the development of their navies practically ceased, and some of the most important vessels, such as the battleships building for Chile and Turkey, were taken over for the British navy.

At the Armistice both the German and Austrian navies ceased to exist as factors in the general naval situation, all their principal ships being surrendered to the Allies, the great majority of the vessels being finally destroyed, either being broken up or used as targets, with the exception of a few of the less important units, such as light cruisers and destroyers, which were incorporated in the French and Italian navies.

Battleships

(1) *United States*.—The first vessels of the "Dreadnought" type constructed for the U.S. navy were the "Michigan" and "South Carolina," launched in 1908. These vessels, carrying only eight 12-in. guns, were of about 2,000 tons less displacement than the "Dreadnought," and 2 knots slower than this vessel. The main armament of the U.S. vessels was disposed, however, in an original manner, constituting a bold departure in that they were all mounted on the centre line of the vessel in two superposed twin-gun turrets forward, and two aft, with large arcs of training on each beam. This arrangement of turrets gave an ahead and astern fire of four guns and a broadside fire of all the eight guns. The water-line armour belt was 11 in. thick with 8 in. above. Cage masts constructed of a large number of steel tubes were fitted in these vessels and such masts have been fitted in all later U.S. capital ships and also in some of the earlier vessels in substitution of their original masts. The "Michigan" and "South Carolina" were propelled by twin screws driven by reciprocating engines, thus differing from the "Dreadnought."

The next battleships built were the "North Dakota" and "Delaware," launched respectively in 1908 and 1909. These vessels were a considerable advance in size over their predecessors, being more than 60 ft. longer, 4,000 tons heavier, and two knots faster, while they carried two additional 12-in. guns. The 10 guns were mounted all on the centre line, the two turrets forward being superposed as in the previous class, while the three turrets aft were arranged so that one could fire over the other two, which were both on the same deck so that one could only fire on either broadside. The arrangement of guns thus increased the broadside fire but left the ahead and astern fire as before. The armour belt consisted of a tier of 11 in. at the water-line, with a tier of 8 in. above. The advance in speed involved an increase of 50% in the H.P. of the engines, viz. from 16,500 to 25,000. Turbines of the Curtis type were installed in the "North Dakota" for the first time in a U.S. capital ship, but the "Delaware" was fitted with reciprocating engines. An important departure in these vessels was the fitting of 14 5-in. guns as secondary armament in a battery amidships, protected by 5-in. armour.

The next pair of battleships, named the "Utah," launched in 1909 and the "Florida," launched in 1910, were enlarged "North Dakotas," but both had Parsons turbine engines of 28,000 shaft horse-power. The tonnage was increased to 21,800 tons on the same draught, and the speed remained practically the same. The length was increased slightly to 521 ft. and the beam to 88 ft. The main armament was the same in number of guns and arrangement of turrets as in the "North Dakota," but the secondary armament was increased to 16 5-in. guns, protected by 5-in. armour. The armour was practically the same as in the previous vessels.

The succeeding pair of battleships, "Arkansas" and "Wyoming," launched in 1911, were characterized by another large increase in dimensions, the length being increased to 562 ft. and the beam to 93 ft., while on the same draught as previous vessels the displacement was 25,000 tons. The engines were Parsons turbines of about 28,000 S.H.P., the speed being about $\frac{1}{2}$ knot less than the "Utah" of the same power but 4,000 tons less displacement. The increased displacement enabled 12 12-in. guns to be mounted

in six twin-gun turrets arranged all on the centre line in three superposed groups, one group forward, another just abaft of amidships and the remaining group aft. The ahead and astern fire thus remained as in previous vessels at four guns, but all 12 guns could be fired on either broadside. The secondary armament was 16 5-in. guns in a 6-in. armoured battery. The protection was generally similar to the previous vessels, the water-line belt and barbette armour being 11 in. thick. The turrets and conning tower were of 12-in. armour.

These vessels were the last U.S. battleships mounting 12-in. guns. The example of the British in fitting 13.5-in. guns in the "Orion" class was followed by the adoption of 14-in. guns in the next vessels laid down by the United States. These were the "Texas" and "New York," launched in 1912, the dimensions of which were slightly greater than those of the "Arkansas" and the displacement 1,000 tons greater. Ten 14-in. guns constituted the main armament and was mounted in five twin turrets, arranged generally in a similar manner to the British "Orion," four guns firing ahead and astern and all 10 on either broadside. The secondary armament remained as before, 16 5-in. guns being mounted in an amidships battery protected by 6-in. armour. The water-line belt was 12 in. thick with a 9-in. belt above it, and the protection generally was somewhat greater than that of the previous vessels. An important feature in these vessels was the return to reciprocating engines, which on a power of 27,000 gave the vessels a speed of 21 knots. The reintroduction of this type of engine was made chiefly to obtain greater economy at cruising speeds.

The next pair of battleships, "Nevada" and "Oklahoma," launched in 1914, were of slightly increased length and tonnage. The main armament was the same numerically as the "New York's," but was arranged in four turrets, two containing two guns each and the other two three guns each. The twin-gun turrets were superposed above the triple-gun turrets at each end of the vessels. The secondary armament of the "Nevada" and "Oklahoma" consisted of 12 5-in. guns arranged in an unprotected battery farther forward than in previous vessels. Turbines were again adopted for the propulsion of the "Nevada," but reciprocating engines were fitted in the "Oklahoma." The reduced power of the machinery, viz. 24,800 H.P. of both vessels, resulted in a reduced speed of 20 $\frac{1}{2}$ knots.

The British example of adoption of oil only as the fuel for the "Queen Elizabeth" class was followed by the United States in the "Nevada" and "Oklahoma," the total quantity of fuel arranged for, however, being 2,000 tons, compared with 3,400 tons in "Queen Elizabeth."

The saving in weight resulting from the adoption of triple-gun turrets and oil fuel enabled considerable additions to be made to the armour protection of the "Nevada" and "Oklahoma." The belt amidships was 13 $\frac{1}{2}$ in. thick and extended from 8 $\frac{1}{2}$ ft. below to 9 ft. above the water-line. The conning tower was protected by 16-in. armour, this being also the thickness of the front plates of the twin-gun turrets, those of the triple-gun turrets being of 18-in. armour. The vessels are further distinguished from their predecessors in that only one funnel, instead of two, is fitted. The uptakes are protected by 13 $\frac{1}{2}$ -in. armour.

FIG. 31.

The "Nevada" and "Oklahoma" were succeeded by the "Pennsylvania" and "Arizona" (fig. 31), launched in 1915, in which the dimensions were further increased and the displacement became 31,400 tons. The main armament was increased to 12 14-in. guns arranged in four triple turrets in two superposed groups forward and aft. The secondary armament originally consisted of 22 5-in. guns, but has been reduced to fourteen. The protection of the vessels was generally similar to that of the "Nevada" and "Oklahoma," but the side armour was increased to 14 in. maximum. Turbine engines were fitted in both vessels of the class, the "Pennsylvania" having geared cruising turbines in order to secure economy.

The "New Mexico," "Idaho" and "Mississippi," launched in 1917, were similar in general design, protection, and main armament to the "Pennsylvania." The displacement was slightly increased to 32,000 tons. The main armament of 12 14-in. guns was again arranged in four triple turrets, with front plates of 18-in. armour, side plates 9 in. to 10 in. and roof plates 5 inches. The

secondary battery of 14 5-in. guns was fitted a deck higher than in "Pennsylvania" and was unprotected.

The "New Mexico" was distinguished from her sister vessels by the adoption of electric motors for her propulsion, the other two vessels having turbines arranged as previously; she had two turbo-electric generating sets of 11,400 kw. capacity installed, and this electric power was transmitted electrically to four motors of, nominally, 6,600 H.P., one on each of the four propelling shafts. These motors were reversible, thus avoiding, as in the ordinary turbine method of propulsion, the necessity for astern as well as ahead prime movers. The electric drive appears to have been successful, especially as the "New Mexico" was not originally designed for this method of propulsion; the accommodation for the machinery being obtained by modifications in the arrangement of the spaces provided in the original design for turbines, without affecting the other features of the design. The vessel was put through exhaustive trials with satisfactory results, a maximum speed of just over 21 knots being obtained at 31,200 H.P. on a displacement of 32,800 tons, with economical steam and fuel consumption. An advantage conferred by the electric drive at cruising ship speeds arises from the ability to obtain the necessary power from only one of the electric generating sets, which can thus be worked at nearly full power and therefore give very good efficiency. The "New Mexico" escorted President Wilson across the Atlantic, and on both eastward and westward voyages only one turbine generating set was used. The weight of the machinery was greater per H.P. than that of turbine machinery of about the same power in British warships, but it was considered that this was capable of improvement in the future, especially in the case of vessels intended from the outset to have the electric drive. The electric drive has been adopted for all succeeding U.S. capital ships.

The "Tennessee" and "California," launched in 1919, were practically repeats of the "New Mexico," the displacement being 32,300 tons. These vessels, however, have two funnels. Also a new system of under-water protection (which has since been adopted for all U.S. battleships) was introduced. This consists of five vertical longitudinal bulkheads extending parallel to the ship's side from the forward to the after magazines, thus protecting the whole of the vitals of the ship. The innermost bulkhead is about 17 ft. inboard, the other bulkheads being approximately equidistant from one another; the bulkheads next to the skin bulkhead and innermost bulkhead are all thin plating, the other three being of thicker plating; the middle three of the five spaces formed by this arrangement are utilized as oil-fuel bunkers.

In Aug. 1915 Congress approved the first building programme ever drawn up for the U.S. navy, according to which 10 battleships, 6 battle cruisers, 10 scouts (or light cruisers), 50 destroyers, 9 fleet and 58 coast submarines were to be added in three years to the U.S. navy, in addition to a number of auxiliary vessels.

The first battleships to be built under this programme were the "Colorado" (launched 1921), "Maryland" (launched 1920 and completed 1921), "Washington" and "West Virginia." The dimensions of these vessels are not greatly different from the "Tennessee," except that the displacement is slightly greater, being 32,600 tons, the H.P. of the electric propelling machinery being increased to 28,900 to maintain the speed of 21 knots. The chief departure in the new vessels was the adoption of 8 16-in. guns as the primary armament, arranged in four twin-gun turrets superposed in pairs forward and aft. The secondary armament consists of 14 5-in. guns. The armour protection is generally as in the "New Mexico" class.

FIG. 32.

The remaining six battleships of the 1916 programme had not yet been launched in 1921. Their names are "South Dakota," "Indiana," "Montana," "North Carolina," "Iowa," and "Massachusetts" (fig. 32). They are a very great advance on their predecessors, being 684 ft. long, 106 ft. wide and displacing 43,200 tons on a draught of 31 feet. An increased speed, 23 knots, is aimed at, the electric drive being of 60,000 horse-power. The main armament is increased by 50%, consisting of 12 16-in. guns mounted in four triple-gun turrets, and the secondary armament comprises 16 5-in. guns. The torpedo armament was two submerged 21-in. torpedo tubes throughout all the battleships described in the fore-

going. In 1919 a second three-year programme was considered, to consist of 156 vessels in all, including a further batch of 10 battleships and six battle-cruisers.

(2) *France*.—The French navy did not immediately adopt the single-calibre main armament, their first vessels, designed after the "Dreadnought" era had begun, being the "Danton" class, which resembled the "Lord Nelson" in armament, 12 9.4-in. guns being carried in addition to the usual 4 12-in. guns. They were about 2,000 tons heavier than the "Lord Nelson" and were fitted with turbines of 22,500 H.P., giving a speed of 20 knots.

The first French battleships of the "Dreadnought" type were the "Jean Bart" class, launched in 1911 and 1912. These vessels, "Jean Bart," "Paris," "France" and "Courbet," were a considerable advance on the "Danton" class, being 546 ft. long, as against 481 ft., with increased beam and draught, and displacement of 23,100 tons. Turbine machinery of 28,000 H.P. was fitted, giving a speed of 20 knots. The main armament comprised 12 12-in. guns mounted in six twin-gun turrets arranged in two superposed groups forward and aft, with the remaining two turrets on the broadsides amidships. The ahead and astern fire was thus 6 guns and broadside 10 guns. The secondary armament was very numerous, consisting of 22 5.5-in. guns protected by 7-in. armour. The side armour was 10½ in. thick, tapering to 7 in. at the bow and stern, the turret armour being also 10½ in. thick.

The "Jean Bart" successfully withstood torpedo attack by an Austrian submarine in 1915, being struck well forward. Compartments were flooded, but the vessel proceeded under her own power to Malta, where she was repaired in H.M. Dockyard.

FIG. 33.

The next battleships built by the French were the "Bretagne" (name ship of the class) (fig. 33), "Lorraine" and "Provence," all launched in 1913, practically repeats of the "Jean Barts," except that the main armament consisted of 10 13.4-in. guns mounted in five twin-gun turrets, all on the centre line of the vessels, the usual superposed groups of two turrets forward and aft, the fifth turret being amidships. The secondary armament again consisted of 22 5.5-in. guns, arranged slightly differently from the "Jean Bart," but this number was decreased after the war to 18, during a partial reconstruction when director-firing was installed on a new tripod foremast.

These vessels were the last battleships completed for the French navy, the completion of the five vessels of the "Normandie" class, launched in 1914 and 1915, having been abandoned, with the exception of the "Bearn," which has been converted into an aircraft-carrier. The "Normandie" class were designed to carry 12 13.4-in. in three quadruple-gun turrets, a unique arrangement. The four guns in each turret were arranged on two mountings, so that virtually they comprised two twin guns. The secondary armament was to have consisted of 18 5.5-in. guns. The machinery intended for these vessels was of an interesting type, consisting of a combination of turbine and reciprocating engines, the two inner shafts being driven by turbines and the two outer shafts by reciprocating engines, which alone were powerful enough to have given the vessels a speed of 16 knots, the full power of 35,000 H.P. being designed to give a maximum speed of 21 knots.

It was intended to have laid down in Oct. 1914 four battleships of the "Duquesne" type, but the outbreak of the war caused this intention to be abandoned. The vessels were designed to carry 16 13.4-in. guns in four quadruple-gun turrets, arranged in two superposed groups forward and aft. The displacement was to have been 29,500 tons, and, with combination turbine and reciprocating engine, a speed of 23 knots was anticipated.

It should be noted that during the whole war period the French Government dockyards, and many private yards also, devoted their whole capacity to the production of munitions of all kinds for the army; naval work being almost entirely relegated to the background. No provision was made in the French naval budget for 1921 for the construction of any capital ships.

(3) *Japan*.—The "Satsuma" and "Aki" were the first battleships built in Japan after the "Dreadnought" era had begun. They were a development of the "Kashima" class, and therefore

resembled in type the "Lord Nelson." Launched in 1906 and 1907, they mounted 4 12-in. and 12 10-in. guns on a displacement of about 19,500 tons. Turbine machinery of 24,000 H.P. was fitted in the "Aki," giving a speed of 20½ knots. The "Satsuma," with reciprocating engines of 18,500 H.P., was 2 knots slower.

The first Japanese battleships of the "Dreadnought" type were the "Settsu," launched in 1911, and the "Kawachi," launched in 1912. The latter vessel was blown up in 1918 in a Japanese harbour by the explosion of her magazines. These vessels were of 20,800 tons and mounted 12 12-in. guns, arranged in six twin-gun turrets, one forward and aft on the centre line and the other four on the broadsides. The ahead and astern fire was thus 6 guns and broadside fire 8 guns. The secondary armament was 10 6-in. guns, mounted in an amidship battery protected by 6-in. armour. Eight 4.7-in. guns were also mounted. The armour belt was 12 in. thick amidships at the water-line and 9 in. above, with 5-in. armour forward and aft, the 12-in. guns were protected by 11-in. armour, and the conning tower by 12-in. armour. Turbine machinery of 25,000 H.P. was fitted, giving a speed of 20½ knots.

FIG. 34.

Large increases in dimensions and power characterized the next class (fig. 34) of Japanese battleships, 14-in. guns being adopted. These vessels were the "Fuso" and "Yamashiro," of 30,600 tons and 40,000 H.P., launched in 1914 and 1915 respectively, and the "Ise" and "Hyuga," of 31,260 tons and 45,000 H.P., launched in 1916 and 1917. The main armament consisted of 12 14-in. guns mounted in twin-gun turrets all arranged on the centre line of the vessel. Two turrets are superposed forward, with a similar arrangement aft, the remaining two turrets being abaft the forward and after funnels respectively. The first pair of vessels named mount 16 6-in. guns, and the second pair 20 5.5-in. guns, as the secondary armament in an amidships battery protected by 6-in. armour. The belt and turret armour is 12 in. thick. The speed of the vessels is about 22½ knots.

FIG. 35.

The next class of Japanese battleships are characterized by the fitting of 16-in. guns. These vessels were "Nagato" (launched 1919 and completed 1920) and "Mutsu" (launched 1920), of 33,800 tons displacement, and "Tama" and "Kaga" (building 1921) of 40,600 tons displacement. The former pair of vessels mount 8 16-in. guns in four twin-gun turrets arranged in the now usual manner, with 20 5.5-in. guns as secondary armament. The latter pair of vessels were probably to mount 10 16-in. guns. The torpedo armament, which in previous vessels consisted of five or six submerged tubes, was increased to eight tubes, four of which are mounted above the water-line. The vessels were slightly faster than previous vessels, a speed of 23½ knots being intended, geared turbines providing the requisite power, which was about 46,000 in the "Nagato" and "Mutsu" and 60,000 in the "Tama" and "Kaga."

Under the 1920-8 Navy Law four battleships were projected. (4) *Germany*.—The "Dreadnought" type of battleship was adopted at once by Germany, the advance from the "Deutschland"

class (of the "Formidable" type) being made without trial as was done in some other navies, of vessels of the "King Edward VII." or "Lord Nelson" types. The first German "Dreadnoughts" were the four vessels of the "Naassau" class, launched in 1908. Shorter but wider and somewhat heavier than the "Dreadnought," the "Naassau," on a displacement of 18,600 tons, carried 12 11-in. guns in six twin-gun turrets, mounted one at each end on the centre line, and two on each broadside, thus giving an ahead and astern fire of six guns and broadside fire of eight. The secondary armament consisted of 12 5.9-in. guns, mounted in a battery protected by 7-in. armour. A large torpedo armament of six 17.7-in. submerged tubes was fitted. The water-line armour belt was 11½ in. thick, with an 8-in. belt above, and tapering to 5 in. forward and 4 in. aft. The speed was 19 knots, the requisite H.P. of 20,000 being developed by reciprocating engines.

The "Naassau" class was followed by the four ships of the "Helgoland" class (fig. 35), launched in 1909 and 1910. These vessels marked a considerable increase in dimensions and displacement. The 12-in. gun was adopted for the first time in these vessels, the Germans claiming that this weapon was the equivalent of the 13.5-in. gun then being adopted by the British in the "Orion" class. The "Helgoland" carried 12 12-in. guns arranged similarly to the 11-in. guns in the "Naassau." The secondary armament was increased to 14 5.9-in. guns and the six submerged tubes were of 19.7-in. diam-

FIG. 36.

eter. The protection was generally the same as that of the "Naassau" class. The speed was increased to 20.5 knots. The various increases involved a displacement of 22,440 tons and engines of 25,000 H.P., but the reciprocating type was still adhered to.

The "Kaiser" class (five vessels), launched in 1911 and 1912, were slightly larger and faster than the "Helgoland" class, being of 24,300 tons and 21 knots, but the main armament was reduced to 10 12-in. guns without loss of broadside fire, as they were arranged similarly to the British "Neptune" (designed two years previously), with one turret forward, two superposed aft and two broadside turrets *en echelon*, all guns thus being able to fire on either broadside. The secondary armament was unaltered and the bow torpedo tube was omitted. The armour protection was considerably increased, the water-line belt being of 13½ in. maximum thickness

FIG. 37.

tapering to 9 in., with an upper belt of 7½ in., the secondary battery above and both ends of the ship being protected by a like thickness. Turbine engines were installed for the first time in German battleships, the power being 28,000 for a speed of 21 knots, which was somewhat exceeded on trials.

The four ships of the "König" class (see fig. 36), launched in 1913 and 1914, were, with the exception of slightly greater dimensions and displacement, generally repeats of the "Kaiser" class in respect of number and calibre of guns and torpedo tubes and of protection. The main armament was arranged all on the centre line, as in the British "Orion" class, the amidship turret being, however, between the two funnels. An important advance lay in the increased oil-fuel (700 tons) capacity, previous vessels having only 200 tons.

The last battleships built by the Germans were the "Baden" and "Bayern" (see fig. 37), launched in 1915, two others of the class not being completed at the time of the Armistice. A very complete description of the "Baden" was given in a paper read by Mr. S. V.

Goodall before the Institution of Naval Architects in March 1921. The "Baden" and "Bayern" were about 3,000 tons heavier than the "König" class, the dimensions being increased proportionately. The chief difference, however, was in the main armament, 8 15-in. guns being mounted in four turrets on the centre line in two superposed groups forward and aft, as in the British "Queen Elizabeth." The secondary armament was increased to 16 5.9-in. guns, and the torpedo armament consisted originally of 5 23.6-in. submerged tubes, one forward in the stem and the other on the broadside forward and aft. The forward torpedo room was damaged by an under-water explosion and when repairs were made the torpedo tubes were not replaced. Turbine machinery of about 50,000 H.P. total was fitted, driving three propellers, and a speed of about 22 knots was obtained on trials. The main armour belt was 13½ in. thick, tapering to 6½ in. at the lower edge. Above was a belt of 10-in. armour extending to the upper deck. The secondary battery was protected by 6½-in. armour. Forward the side armour was 6 in. thick and aft 7 inches. The latter and a deck of 4½ in. thickness provided protection to the steering gear. The maximum thickness of armour for the barbettes, turrets, and conning tower was 13½ inches. Protection against under-water attack was provided by a longitudinal bulkhead 2 in. thick, set in about 13 ft. from the side.

(5) *Italy*.—The first Italian "Dreadnought" was the "Dante Alighieri," of 19,200 tons, launched in 1910. This vessel was then remarkable for the high designed speed of 23 knots and the adoption of triple-gun mountings for the main armament of 12-in. guns, of which 12 were carried in turrets all fitted on the centre line of the vessel. The turrets, funnels and masts were so disposed that the vessel could practically be described as "double-ended." The vessel was protected by a water-line belt of 10-in. (maximum) armour amidships and 4-in. at the ends, with an upper belt of 6-in., by which 12 of the secondary battery of 20 4.7-guns were protected. The remaining 8 4.7-in. guns were mounted in four twin-gun turrets on the upper deck. The 12-in.-gun turrets had a maximum thickness of 10-in. armour. Turbine engines of 26,000 H.P. were fitted; these developed 35,000 I.P. on trial, when 24 knots were attained. Three torpedo tubes were fitted.

The "Dante Alighieri" was followed by the "Conte di Cavour," "Leonardo da Vinci" and "Giulio Cesare," launched in 1911. These vessels were 3,000 tons heavier than their predecessor and mounted an extra 12-in. gun, making 13 in all, four of which were in two twin-gun turrets superposed above triple-gun turrets forward and aft, a further triple-gun turret being fitted amidships. This arrangement enabled an increased all-round fire to be obtained over the previous vessel. The secondary armament of 18 4.7-in. guns was carried in an amidships battery protected by 5-in. armour, which was above the upper belt of 9-in. armour, the water-line belt being 10-in. amidships and 4-in. at the ends. Turret armour was 10-in. and conning tower 12-inches. Turbine engines of 24,000 H.P. were fitted to give a speed of 22 knots.

FIG. 38.

The "Andrea Doria" and "Caio Duilio" (see fig. 38), launched in 1913, were slightly longer and heavier than the "Conte di Cavour," but except for an improved secondary armament of 16 6-in. guns fitted abreast the forward and after turrets, the changes were of a minor nature.

The "Leonardo da Vinci," blown up at Taranto in 1916 by the explosion of her magazine, was refloated and dry-docked upside down in 1919. After repairs she was floated out of dock still upside down and then righted. This operation reflects the greatest credit upon the Royal Italian Corps of Naval Constructors, who conducted the operations throughout. The vessel, will, however, not be restored as a warship, but utilized for a subsidiary service.

The last four battleships laid down in 1914 and 1915 for the Italian Navy, the "Caracciolo" class, have not been completed. They were to have been generally similar in size, armament, speed and protection to the "Queen Elizabeth."

(6) *Russia*.—The Russian navy has ceased to exist as an important factor, but technically the various classes of battleships built are of interest.

Following the construction of two vessels of the intermediate "Lord Nelson" type, four battleships of the "Petrovavlovsk"

class were launched in 1911 and three of the "Imperator Alexander III." class (for the Black Sea Fleet) in 1914. The first four were slightly heavier, longer and faster than the others, but their general characteristics are similar. They all mount 12 12-in. in four triple-gun turrets on the centre line of the vessel, arranged similarly to the Italian "Dante Alighieri," the speed of which, 23 knots, was the same as that of the "Sevastopol," the Black Sea vessels being 2 knots slower, all the vessels having turbine engines.

The "Imperatritza Marie" was blown up by an internal explosion at Sevastopol in 1916, and refloated and docked upside down in 1919, similarly to the "Leonardo da Vinci."

(7) *Austria*.—Three battleships of intermediate ("Lord Nelson") type were completed in 1910 and 1911. Following these vessels four "Dreadnoughts" of the "Viribus Unitis" class were completed in 1912-5. On a displacement of 20,000 tons, 12 12-in. guns in four triple-gun turrets (of 11-in. armour maximum) were carried in two superposed groups forward and aft with 12 5.9-in. guns as secondary armament in an amidships battery protected by 6-in. armour. The water-line belt was 11 in. amidships and 5 in. at the ends. An upper belt of 8 in. was fitted amidships. Turbine engines of 25,000 H.P. gave a speed of about 20 knots.

Two vessels, the "Szant Istvan" of this class and the old battleship "Wien," were sunk during the war as the result of daring attacks by Italian fast motor-boats. The "Viribus Unitis" sank in 1918, due to the explosion of a mine placed in contact with the vessel by two Italian officers in a small torpedo-like motor-boat.

A contemplated programme of four battleships of 25,000 tons, carrying eight 15-in. guns, did not materialize owing to the war.

(8) *Argentina*.—The only "Dreadnought" battleships are the "Moreno" and "Rivadavia," launched in the United States in 1911 and completed in 1914; 12 12-in. guns, in six twin-gun turrets, and 12 6-in. guns are carried on a displacement of 27,600 tons, turbine engines of 39,500 H.P. giving a speed of 22½ knots.

(9) *Brazil*.—The "Rio de Janeiro," laid down at Armstrong's, Newcastle, in 1911, was sold later to Turkey, from whom the vessel was requisitioned by the British on the outbreak of the World War, and renamed "Agincourt." The "Minas Geraes" and "São Paulo" are thus the only two "Dreadnought" battleships possessed by Brazil.

(10) *Chile*.—The "Almirante Latorre" and "Almirante Cochrane" were building at Armstrong's in 1914 for the Chilean navy. The former vessel, after service during the war as H.M.S. "Canada," was sold back to Chile, but the latter vessel remains as H.M.S. "Eagle." Chile thus possesses only one "Dreadnought."

(11) *Greece*.—The "Salamis," of 19,500 tons and 23 knots speed, building in Germany at the outbreak of war in 1914, had not been completed. The four twin-gun turrets constructed in the United States for this vessel were purchased by the British and fitted in the first four large monitors.

(12) *Norway*.—The "Nidaros" and "Bjorgvin" (coast-defence battleships), launched by Armstrong's in 1914, were taken over by the British during the war and completed, with the addition of bulges, as H.M.S. "Clatton" and "Gorgon."

(13) *Spain*.—The smallest "Dreadnought" battleships ever designed have been completed for the Spanish navy. On a displacement of 15,500 tons, the "Alfonso XIII.," "España," and "Jaime I." carry 8 12-in. guns in four turrets (the amidships turrets being *en echelon*) and 20 4-in. guns. Turbine engines of 15,000 H.P. give a speed of 19½ knots. Armour protection consists of a 9-in. water-line belt, with 10-in. armour for the turrets and conning tower. The vessels were built in Spain from designs and under the supervision of British firms.

(14) *Sweden*.—Three small battleships, the "Sverige" (completed in 1917), and the "Drottning-Victoria" and the "Gustav V." (which in 1921 were nearing completion), are of 7,600 tons displacement. They mount four 11-in. and eight 6-in. guns, and with turbine engines of 22,000 H.P. a speed of 22 knots is expected.

(15) *Turkey*.—Two battleships completing in England for the Turkish navy were taken over by the British Government on the outbreak of war and renamed "Agincourt" and "Erin."

Battle Cruisers

Up to 1921 battle cruisers had been built only for Japan, Germany and Russia, besides Great Britain (see Table V/1.). The United States had six vessels building.

United States.—The "Lexington" class (fig. 39) were designed in 1916, but no progress was made in their construction during the war. After the Armistice their design was reconsidered. The displacement was increased from 35,300 tons to 43,500 tons, the main armament being changed from 10 14-in. guns to 8 16-in. guns. The S.H.P. was 180,000 total, driving four propellers, and this was estimated to give 35 knots as the original design displacement and 33½ knots for the final design. This enormous H.P. (the maximum so far contemplated for any ship) is developed by the electric drive, on generally similar but improved lines to that of the "New Mexico." Oil fuel only is burnt in the boilers. The changes made included considerably increased protection against gunfire and under-water attack. The result of all the changes made is that the vessels will be powerful battle cruisers, with good offensive and defensive qualities as compared with the initial design. The torpedo

armament is very large for a U.S. vessel, consisting of four submerged and four above-water 21-in. torpedo tubes. The vessels had yet been launched in 1921.

Russia.—Four battle cruisers were launched in 1911, with a main armament of 8 16-in. guns. They had not been completed up to 1921. On a displacement of 10,000 tons, with a length of 750 ft., 12 14-in. and 24 5-in. guns. As with the "Dreadnought" type of battleship, the British in their battle cruisers. The first

FIG. 39.

pedo tubes were to have been carried, turbine engines being estimated to give a speed of 27 knots. The side maximum thickness of 12 inches.

Japan.—The "Tsukuba" and "Ikoma" were 1905 and the "Kurama" and "Ibuki" in 1907. They were classed as battle cruisers, but they lacked the high speed and the essential feature of the battle-cruiser type. The "Tsukuba" was blown up in a Japanese harbour in 1911.

FIG. 41.

FIG. 40.

battle cruisers built by Japan were the four vessels of the "Lion" class, launched in 1912-3, the name ship being consigned to the scrapyard, as well as other battle cruisers of the "Lion" class, and her sisters in Japan. These vessels had not been far advanced. The "Lion" class, having an armament of 8 14-in. and a displacement of 27,500 tons, a speed of 27 knots, and turbines developing 64,000 horse-power. The "Lion" type of warship has in recent years been constructed by very few nations (see Table VIII.). The United States

Light Cruisers

a displacement of 27,500 tons, a speed of 27 knots with turbines developing 64,000 horse-power. The cruiser type of warship has in recent years been con-
protected by 10-in. (maximum) armour, and they very few nations (see Table VII.). The *United States*

SHIP AND SHIPBUILDING

Table XII. includes a number of very fine vessels which Germany was building in 1914 to compete with the "Aquitania," "Olympic," and such types of British ships, in order to gain a still larger proportion of the Atlantic trade. Amongst them were the largest vessels afloat in 1921. In certain cases German companies were afterwards enabled to repurchase from the Allies some of the surrendered ships, which then reverted to German ownership. Austria had to surrender all her shipping, about 1½ million tons. This was handed over to Italy, with the exception of about 70,000 tons for France.

Statistics.—The world's output had reached a maximum of 3,330,000 tons in 1913, and was falling again in 1914. The tonnage

launched in the United Kingdom reached the record total of approximately 2,000,000 tons in 1913, and in 1914 it had decreased by over 10 per cent. Great efforts had been made in France, Germany, Holland, Japan and Norway, and the totals in these countries showed distinctly upward tendencies. In the United States very great fluctuations occurred; the output on the coast had fallen to 95,000 tons, and on the Great Lakes to 75,000 tons in 1911, while in 1913 228,000 tons were launched on the coast and only 48,000 tons on the Lakes.

Table XIII. shows the tonnage of ships launched in various countries from 1910-20. The diagram Fig. 44 has been prepared on the basis of these figures. The striking results obtained in the British colonies and Japan will be noted, and the overwhelming influence of U.S. shipbuilding. Many of the American yards which were specially constructed for war purposes were in 1921 being closed,

SHIP AND SHIPBUILDING

445

while others were falling back rapidly to pre-war conditions (see SHIPPING: United States).

In the United Kingdom, from the middle of 1915, a committee of the Board of Trade, in conjunction with the Transport Department of the Admiralty, assumed control of the British mercantile marine, including shipbuilding. A Merchant Shipbuilding Advisory Committee was formed, with Sir George Carter as chairman. In Dec. 1916 the Ministry of Shipping was set up, under Sir Joseph Maclay. The Shipbuilding Advisory Committee was enlarged, and on its advice steps were taken to standardize the types of merchant ships to be built, and to simplify the details of construction both of hull and machinery to secure the greatest and quickest output possible.

Five types of "standard ships" were designed, varying from 3,000 to 8,000 tons deadweight, and between Dec. 1916 and April 1917 considerable numbers of these vessels were ordered. In order to harmonize the work of shipbuilding for the Admiralty and the mercantile marine, the whole was placed under one authority, Sir Eric Geddes, in June 1917, when he assumed office as controller of the Navy. Arrangements were made for setting up new shipyards with a view to producing "fabricated" ships, which could be put together with very much reduced amounts of skilled labour; but the results were disappointing, and at the end of 1918 the output in the United Kingdom was still only at the rate of 1,500,000 tons per annum. In March 1918 Lord Pirrie was appointed controller-general of

Total, World's Shipping	41.8	49.1	50.9	57.2	62.0

Largely as a result of the efforts of the United States, by the end of 1918 ships were being built at the rate of 7,000,000 tons per annum, against the pre-war record of 3,330,000 tons per annum. In June 1920 the steam tonnage of the world amounted to about 54,000,000 tons, notwithstanding the losses of the war. The total losses had amounted to about 9,000,000 tons of British ships and 6,000,000 tons others, making a total of 15,000,000 tons. Of the total, 2,000,000 tons were due to ordinary marine risks.

FIG. 44.

Motor-Ships.—The period 1910-21 saw immense changes in the means of propulsion. In 1911 the "Selandia" and "Jutlandia" were launched, and a number of other vessels were being built, in which internal-combustion engines of a more or less experimental character were being fitted. *Lloyd's Register* reports that by 1914 there were 200 motor-ships of 234,000 tons gross, while in 1921 there were no fewer than 1,447 ships of 1,263,000 tons gross, so that in 1921 there were nearly five times as many motor-ships in existence as there were in 1914, and the tonnage of these ships was nearly six times as great. In these seven years motor-vessels increased from .47 to 2.1 per cent of the world's tonnage.

Dr. Diesel's master patents expired in 1909 and 1910, and since then many successful types of internal-combustion engines have been established in Europe and in America (see INTERNAL-COMBUSTION ENGINES), and the proportion of motor to steam vessels building rapidly increased. In June 1921 183 motor-vessels of 502,944 tons were under construction, and out of this number 57 of 241,003 tons were being built in the United Kingdom.

Oil Burners.—Another very great improvement is in the use of oil instead of coal under steam boilers. *Lloyd's Register* reports that in 1914 364 vessels of 1,310,000 tons were fitted to burn oil, but in 1921 these had increased to 2,563 ships of 12,797,000 tons, or from 2.62 to 20.65% of the world's tonnage. In the United States four vessels burn oil to every three vessels burning coal. This use of oil fuel has demanded a large increase in the number of oil-tank steamers. In 1914 there were 385 tankers of 1,479,000 tons, while in 1921 there were 861 tankers of 4,419,000 tons, an increase from 2.94 to 7.16 per cent of the world's tonnage.

Electric Drive.—It has been the almost universal practice for submarines to be propelled by electric motors when submerged. In a few cases of small surface vessels electric drive had also been used prior to 1910. The earliest recorded appears to be Nobel's tank vessel "Sarmat," fitted with the system in 1904. About 1910 a small vessel named the "Electric Arc" was built on the Clyde to test the method of electric transmission devised by Mavor, using Squirrel cage motors. The experiment was not altogether a success, but it gave a good deal of experience. Mavor proceeded to America and discussed his ideas with Emmet, and no doubt assisted Emmet in the great undertaking carried out for the American navy in the collier "Jupiter" (now aircraft-carrier "Langley"). The American navy built three colliers at this time of identical dimensions, about 20,000 tons displacement, 7,500 H.P., 15 knots full speed, and cargo 12,000 tons. The "Cyclops" has two reciprocating engines, the "Neptune" has Parsons turbines and a West-

inghouse floating frame mechanical gearing, while the "Jupiter" was fitted with a Curtis turbo-electric generator, running at 2,000 revolutions, giving alternating current at 2,200 volts, and motors driving two propeller shafts at 110 revolutions. The reported engine room weight of the "Jupiter" is 223 tons, compared with 343 tons in "Cyclops" and 189 tons in "Neptune."

Mavor's next step was to fit up an installation of 1,500 S.H.P. in the "Tynemouth," built by Messrs. Swan, Hunter & Co. in 1913. This vessel was 250 ft. long, 1,644 tons gross, and of about 8 knots speed. This system, however, did not admit of development on a large scale.

The next important progress was made in Sweden, where two sister vessels were built, 225 ft. x 36 ft. x 15½ ft., 2,250 displacement, 975 tons gross. Each was provided with 900 H.P. for 11½ knots. In the "Mimer" triple expansion reciprocating engines were fitted. In the "Mjolner" Ljungström turbo-generators running at 800 r.p.m. were fitted, with two motors of 450 H.P. each, and geared to a single propeller shaft running at 85 r.p.m. It was reported that fuel consumption was reduced by over 40%, to .89 lb. per I.H.P. per hour, and that a saving of 74 tons in weight was effected. A large number of other vessels have since been fitted on the "Ljungström" system. These include the "Turbinia," of 2,250 tons and 1,020 H.P., built in 1916 in Sweden, and the "Wulst Castle," of 3,566 tons and 1,500 S.H.P., built in 1918 by Blumer of Sunderland. It was reported that in 1921 there were 40 vessels building in different countries on this system with the aggregate of 70,000 horse power.

The success of the "Jupiter" was so great that electric transmission was adopted by the U.S. navy for a great many of their later ships, even of the highest power. The next great experiment in electrical propulsion was put in hand by the U.S. Shipping Board, who decided to remove the mechanical gearing in 12 vessels and fit an electric drive instead. The first vessel taken was named "Eclipse," the next three vessels "Archer," "Independence" and "Victorious." The "Eclipse" is 440 x 56 x 35.2, of 7,589 tons gross and 11,900 dead-weight. The boilers are fitted with Dahl oil burners, steam 215 lb. and 200° super heated. One turbine of the Curtis Impulse type is fitted to run at 2,000 r.p.m. A three-phased generator supplies current at 2,300 volts. An induction motor is fitted directly on the propeller shaft working at 2,300 volts and running at 100 r.p.m. for 3,000 H.P. The speed may range from 20 to 110% of the normal. The result of the trials was very gratifying. The reports as to the first voyage were not quite so good. The other three vessels named had not yet gone on service in 1921.

Another very interesting case is that of the "Cuba," a vessel 310 x 40 x 26.9 of 2,963 tons gross. This vessel has also been fitted with a turbine electric drive by the General Electric Co., Schenectady, but in this case a synchronous motor is fitted. Steam of 190 lb. with 200° super heat is supplied to an 8-stage Curtis turbine, as in "Eclipse." This runs at 3,000 r.p.m. and 1,150 volts. The motor gives 3,000 H.P. at 100 r.p.m. and 1,150 volts, and is fitted directly on the shaft. The trials of this vessel were well reported on. Both vessels are of 11 knots speed.

The question of the efficiency and economy of the electric drive was being very much discussed in 1921. On the one hand it was said that the transmission loss of the electrical system was 8% instead of 3% with the mechanical current, but the other ships with electrical current reported very good economy of fuel.

Wood Vessels.—In 1914 wood vessels amounted to 1% of the total steam tonnage, but owing to the special building during the war it had risen to nearly 4% in 1921. Of this large increase the United States owns one million tons.

The Emergency Fleet programme provided for ordering 1,067 wooden and composite ships, of 3,227,200 tons; but only 607 of 1,948,250 tons, were actually produced. In June 1921 288 cargo carriers remained in the possession of the U.S. Shipping Board, 15 being on active service and 273 tied up. The board also had 14 tugs, of which 9 were on active service. Up to this date 211 had been sold, 12 of which had been built for service as cargo carriers and 61 as tugs. One had been fitted for carrying oil in bulk. Seventy-four were incomplete when sold. In Aug. 1921 the remaining wooden vessels were reported to be sold to the Ship Construction and Trading Company.

Concrete Ships.—Prior to the war a number of small vessels for harbour or river service had been built of ferro-concrete in Italy, Norway and France. During the war a few experimental vessels of small size were built in various places, and the system was adopted to an increasing extent, practically all over the world. As larger vessels were built, the methods received careful consideration, and by proper development vessels up to 7,500 tons dead-weight were successfully produced. The complication of rods and ties in the larger vessels became very great, and sectional or panel systems were introduced, as contrasted with the usual monolith system. The reports as to results varied. The weight of hull was reported to be from 50 to 100% more than for steel, or about equal to wood; while the saving of steel for carrying a given dead-weight amounted to 55 to 66% of the steel ship. This was an enormous advantage during the steel shortage, and a further advantage was the power to build by a new class of labour, giving a greater aggregate of labour for shipbuilding. The most notable vessel was perhaps the S.S. "Faith," built by the San Francisco Shipping Co. in 1918.

This vessel, 320 ft. long, 3,427 tons gross, and fitted to burn oil fuel, was a great success. On arrival in England with a cargo the holds were found to be absolutely dry. Table XV. gives the total tonnage recorded of vessels of this type.

TABLE XV.—*Ferro-Concrete Vessels Included in "Lloyd's Register," 1921-2.*

Country	Steam and Motor Vessels		Sailing Vessels		Total	
	No.	Tons	No.	Tons	No.	Tons
United Kingdom	13	4,222	46	31,625	59	35,847
Canada (coast)	1	320	1	320
United States (sea)	15	73,894	15	73,894
Denmark	3	2,413	3	2,413
France	3	2,383	1	816	4	3,199
Italy	3	602	3	602
Norway	14	6,093	14	6,093
Spain	1	273	1	273
Total	50	89,598	50	33,043	100	122,641

Large Liners.—Particulars of notable Atlantic liners of recent construction are given in Table XVI. When the "Lusitania" was sunk during the war, the "Mauretania" (30,704 tons) was the only pre-war 25-knot Atlantic liner left. She was followed, however by the "Aquitania" (45,647 tons), of 24 knots, launched by John Brown & Co., for the Cunard Co., in 1914, and the "France," of 23,666 tons gross, launched at St. Nazaire for the Cie. Générale Transatlantique in 1912. The "France" had turbines of 45,000 H.P. on four shafts for her 24 knots, and carried 1,926 passengers besides her crew of six hundred. The "Aquitania" was completed during the war as a hospital ship, but saw very little service as such. After the war she was overhauled and fitted to burn oil fuel, so as to carry 3,250 passengers.

In 1917 another great French liner was launched, the "Paris," of 33,700 tons; it was not completed until June 1921. She could carry 98 passengers in cabins de luxe, 468 first-, 464 second-, 1,100 third-class (in cabins), also 1,100 steerage in open berths—the total, including crew, amounting to 3,900 persons. She was fitted with four screws driven by Parsons' turbines, manufactured at Havre. During completion she was modified to burn oil fuel on the Wallend-Howden system. On her first trip, with 12 boilers out of 15 in service, she averaged 21 knots.

Of the great White Star liners, the "Adriatic," of 24,541 tons gross, capable of carrying a total dead-weight of cargo and fuel of 19,710 tons, at a speed of 18½ knots, may be taken as typical. A later ship, the "Belgic," of 24,547 tons gross, which was put prematurely into service during the war (1917), could carry 22,025 tons at the same speed. The "Adriatic," "Baltic," "Cedric" and "Celtic," averaging 22,600 tons gross, with a total dead-weight capacity of over 55,000 tons, became well known to Atlantic passengers as the "Big Four."

The White Star policy of combining comfort for passengers with a large cargo-carrying capacity found its highest expression, however, in the "Olympic," of 46,359 tons, launched by Harland & Wolff in 1911. She could carry a total of 12,770 tons dead-weight on a draught of 34 ft. 7 in., with a displacement of 52,300 tons, and could take 2,400 passengers, besides her crew of 900, across the Atlantic at 21 knots. Having been altered to burn oil fuel, she could take sufficient at New York (7,500 tons) to provide for the double journey. Her maximum speed is 22½ knots at 55,000 horse power. The "Olympic" was in 1921 the biggest British-built vessel, but her dimensions had been exceeded by the "Britannic," of 48,158 tons, which was launched by Harland & Wolff in 1914, and was sunk in Greek waters while serving as a hospital ship in 1916.

Still larger, however, were the three great liners built in Germany during 1912-4. The largest of these (and in 1921 the largest in the world), the "Majestic," (fig. 45) launched by Blohm & Voss in 1914, and acquired by the White Star for entering service in 1922, is of 56,000 tons gross. Turbines of about 100,000 H.P. on four shafts, the greatest installation yet fitted in any merchant vessel, give her an ocean speed-capacity of 23 knots. She is 956 ft. in length, 100 ft. in width, and 102 ft. in height from keel to boat deck. Parsons' turbines, arranged for triple expansion, are fitted on four shafts, and steam is supplied by Yarrow water-tube boilers at 260-lb. pressure. The machinery weighs 8,500 tons, and 5,700 tons of fuel are consumed on one trip. The funnels come up at the side of the ship, joining together above, and thus leave the central part clear for dining-halls, etc. The ventilation involves 18 m. of piping, while there are 15,000 electric lamps, and 225 electric motors for various purposes, requiring a total of 1,565 horse-power. She can carry 4,000 passengers, while the food for one voyage includes 12 tons of fresh meat, 12 tons of vegetables, 14 tons of milk and about 5 tons of eggs.

Amongst the latest additions to the White Star line up to 1921 was the "Homeric," of 35,000 tons, carrying 2,700 passengers at 21 knots; she was launched at Danzig in 1913 as S.S. "Columbus." The "Homeric" is notable as being the last large ship propelled by reciprocating engines only, of which she has two sets, triple expansion,

cyls. 50½ in., 86½ in. (2), 96 in. and 70 in. stroke; but these were exceeded in size by those of "Britannic," (fig. 46) which were 54 in., 84 in. (2), 97 in. and 75 in. stroke, to give 32,000 I.H.P. on two wing shafts, and in addition "Britannic" had 1-p. turbines to give 18,000 S.H.P. on two central shafts. The engines of "Britannic" were probably the most powerful single sets made for an ocean liner, while the "Kronprinzessin Cecilie" (now "Mount Vernon") had the greatest total I.H.P., as she had two sets of 4-cyl. engines on each shaft; they were 37½ in., 49 in., 75 in., and 112 in. (quadruple expn.) and 71 in. stroke. Other new vessels being added by the White Star line are:—"Regina" (16,314 tons), and "Rimouski" (9,281 tons) for Canadian service; "Laurentic" (18,000 tons), "Doric" (16,600 tons) and "Pittsburgh" (16,600) for U.S. services.

The Cunard Co. acquired the "Berengaria" (formerly "Imperator") of 52,022 tons, launched by Vulcan Works, Hamburg, in 1912. This vessel has Parsons' turbines of 60,000 H.P. on four shafts and can attain a speed of over 22 knots with 185 revolutions. She carries 4,000 passengers and a crew of 1,200.

The Cunard Co. decided immediately after the war to build a large number of intermediate vessels somewhat of the "Olympic" type, but smaller and of less speed. The first four were 600 ft. ships of about 21,000 tons gross and 27,000 tons displacement, at 30-ft. draught, and were named "Scythia," "Samaria," "Franconia," "Laconia." The "Samaria," (fig. 47) which may be taken as typical, was built by Cammell Laird & Co. in 1921. Her engines (turbines) are fitted with double helical speed reduction gear, to drive the propellers at an economical speed. The boilers are of the cylindrical type, fitted to burn oil fuel with forced draught on the Wallend-Howden combined system. They will give steam at 220 lb. with 200° F., superheated by means of Schmidt's smoke-tube type of superheater. Her twin screws are operated by Brown-Curtis turbines, which run at 2,750 revolutions. Triple expansion is arranged for as follows: On each side of the ship a I.H.P. and 1-p. turbine are fitted in tandem on the shaft of the first driving pinion, and the 1-p. turbine is fitted on the shaft of the second driving pinion of the first reduction gear, both then operate through the second reduction gear and give the propeller shafts a speed of 90 revs. per minute. The total S.H.P. of 13,500 gives a sea speed of 16 knots. The stern turbines are compound, and are incorporated in the exhaust casings of the intermediate and low-pressure ahead turbines, and give a total power equal to about 70% of the ahead power. This may be taken as typical of the best turbine arrangements of 1921. The "Samaria" can carry about 350 first-, 350 second- and 1,600 third-class passengers. Her deck machinery is driven by electric power through hydraulic variable-speed gear at each of the machines. Two large sets of turbo-driven generators are provided for this purpose, and an oil-driven emergency dynamo is also fitted. A gyro-compass installation is fitted, the master compass being on one of the lower decks, with three separate controlled compasses at suitable positions for navigation. Her subdivision is on the most approved principle, with increased numbers of water-tight bulkheads, the water-tight bulkhead doors being operated on the Stone-Lloyd hydraulic system. She is further subdivided by fireproof bulkheads, and the "Grönwald" system of fire extinguishing is installed. Electric passenger hoists are provided.

Among great pre-war German liners which came into the service of U.S. shipping companies were the "America," of 17½ knots and 22,622 tons, launched by Harland & Wolff, Belfast, in 1905, and the "George Washington," (fig. 48) of 18 knots and 25,570 tons, launched by the Vulcan Works, Stettin, in 1908. In addition, the "Leviathan," of 54,282 tons, and 21 knots, launched by Blohm & Voss, Hamburg, in 1914, was still in 1921 awaiting renovation and allocation to service. During the war these great vessels were utilized to transport immense numbers of American troops across the Atlantic. For this service they were specially prepared and ballasted, and, on sailing, the "Leviathan" had what may perhaps be a record draught for a vessel leaving port, viz. 40 ft. 11 in. "Leviathan" carried as many as 11,000 troops on a single trip.

Among American liners the place of the old "St. Paul" has been taken by ships of the "State" class, which were started as 522-ft. troopships (fig. 49). The first on the Atlantic service were the "Panhandle State," and the "Old North State," vessels of 10,500 tons, completed in 1920. There were five other vessels also of the same type, 522 ft. overall, with 502 ft. between perpendiculars. Supplemented by the great ex-German ships named above, they enabled the Shipping Board to send their faster (535 ft.) State type of vessel to the Pacific.

Germany in 1921 retained the old "Deutschland," which had now only machinery for 15½ knots, and was named "Hansa." Just prior to the war Germany was building a series of splendid vessels, most luxuriously fitted out, and supplied with every modern device for the attraction and comfort of passengers in order to capture the S. American trade. They were fitted with a combination of reciprocating engines and turbines. The best-known vessel, "Cap Trafalgar," 18,710 tons, 17½ knots (1913), was an armed merchant cruiser, met and sunk after a stiff fight by the Cunarder "Carmania," also fitted out as an armed merchant cruiser. Other vessels of the type were the "Cap Finisterre," 14,503 tons, 17 knots, (1914) (now the "Taiyo Maru"), and the "Cap Polonio," 19,500

tons, 18 knots (1914). The last had specially luxurious apartments to fit her for the use of the ex-Kaiser, but after the war British owners could not run her at a profit, and she was sold back to Germany, and was, in 1921, far the best and fastest German steamer.

France replied with the "Lutetia," 14,654 tons (1913), and the "Massilia," 15,147 tons (1914), both having a combination of reciprocating engines and turbines for 20 knots.

The "Esperia," of 11,393 tons, the finest passenger vessel built as such in Italy, was launched at Genoa in 1921. She is fitted with Parsons' turbines, of 19,600 H.P., on two shafts, with mechanical reduction gearing, for 21 knots, and carrying 480 passengers in addition to a crew of three hundred. Italy also ordered two fine vessels in Great Britain. One, the "Conte Rosso," built by Beardmore, Dalnair, was requisitioned by the Admiralty, razed to give an uninterrupted flat deck, with no funnels, and fitted out as the aircraft-carrier "Argus." She was finished just before the Armistice. To take her place another vessel of the same name was launched in 1921 by Beardmore, 15,500 tons, 18½ knots speed, dimensions 570 ft. x 74.2 ft. x 36.1 feet. The second vessel, "Giulio Cesare," laid down by Swan, Hunter & Co. at Wallsend, stood half plated during the war, and was finally completed in 1920, 21,500 tons, 18½ knots sea speed. In her the fitting-out of the German "Cap" vessels was rivalled by a combination of British and Italian art, and this vessel was in 1921 the largest and finest Italian liner, and the

finest vessel trading to S. American ports. She has four sets of turbines of 21,900 H.P. with single reduction gearing driving four propellers, giving a speed of 19½ knots speed on trial, and carries 243 passengers in *de luxe* state-rooms, 306 second-class, 800 steerage and a crew of 520, giving a total of 1,869.

Spain had two fine vessels built just before the war, the "Infanta Isabel de Borbon," of 10,348 tons, 17½ knots, launched by Denny at Dumbarton (1913), and the "Reina Victoria Eugene," 10,137 tons, launched by Swan, Hunter & Co. (1913), 17½ knots, and of about the same general dimensions. Both are fine well-fitted vessels, and both have a combination of reciprocating engines and turbines of 10,000 H.P. for propulsion at 17½ knots speed. Spain also built herself vessels of a steadily improving class. The "Alfonso XIII." (of 10,137 tons gross), built in 1921 at Bilbao, was the finest vessel yet constructed in Spain. Her dimensions are 480 ft. x 61 ft. x 41 feet. She is fitted with two sets of geared steam turbines of 10,300 S.H.P., giving 14 r.p.m. at the propellers, and a speed of about 17½ knots.

Particulars of notable recent Pacific liners are given in Table 17. The wonderful development of what might be spoken of as secondary liners is illustrated by the new vessels built for the Canadian Pacific railway (now Canadian Pacific Ocean services). The "Empress of Canada," of 22,000 tons and 22 knots, built in 1920 by Fairfield will be the finest vessel on the Pacific Ocean.

TABLE XVI.—Particulars of Notable Atlantic Liners.

Name	Tons gross	Speed Knots	Owners	Date of build.	Dimensions L B D	Builders	Dead-weight Tons	Horse-power	No. of screws	Types of Machinery and Makers	Steam pressure lbs.
"Mauretania"	30,704	26.0	Cunard Co.	1907	762.2 x 88 x 57.1	Swan Hunter, Newcastle.	12,280	79,000	4	Parsons' turbines Wallsend Slipway Co.	195
"Aquitania"	45,647	24	Cunard Co.	1914	868.7 x 97 x 49.7	J. Brown, Clydebank, Glasgow.	12,913	60,000	4	Steam turbines J. Brown, Clydebank.	195
"Heterogaria" (ex "Imperator")	31,022	22½	Cunard Co.	1912	882.0 x 98.3 x 57.1	Vulcan Werke, Hamburg.	12,000	60,000	4	Steam turbines Vulcan Werke, Hamburg.	...
"Scythia"	10,501	16	Cunard Co.	1921	400.7 x 73.8 x 40.7	Vickers, Barrow.	12,400	2	Steam turbines Vickers, Barrow.
"Samarra"	20,937	16	Cunard Co.	1921	601.5 x 71.7 x 40.7	Cammell Laird, Birkenhead.	12,400	11,500	2	Brown, Curtis turbines with double reduction gear. Cammell Laird.	220
"Britannic" (lost in World War).	48,158	White Star Co.	1914	852.5 x 91 x 59.5	Harland & Wolff, Belfast.	50,000	3	Reciprocating & l.p. turbine Harland & Wolff.
"Olympic"	46,430	22	White Star Co.	1911	852.5 x 92.5 x 50.5	Harland & Wolff, Belfast.	12,770	50,000	3	Reciprocating & l.p. turbine Harland & Wolff.	215
"Majestic" (ex "Bismarck")	56,000	21	White Star Co.	1914	912 x 100 x 57.1	Blohm & Voss, Hamburg.	100,000	4	Steam turbines Blohm & Voss, Hamburg.
"Belgic"	24,547	18½	1917	670.4 x 78.4 x 44.7	Harland & Wolff, Belfast.	22,025	3	Reciprocating & l.p. turbine Harland & Wolff.
"Homeric" (ex "Columbus")	35,000	19	White Star Co.	1913	750 x 83 x 48.0	F. Schichau, Danzig.	2	Reciprocating F. Schichau, Elbing.
"America" (ex "Amerika")	22,622	16.7	U.S. Government (War Department)	1905	668.8 x 71.3 x 47.8	Harland & Wolff, Belfast.	20,765	17,500	2	Reciprocating Harland & Wolff.	220
"Leviathan" (ex "Vaterland")	34,282	22½	U.S. Government (Navy Department)	1914	607.6 x 100.3 x 58.2	Blohm & Voss, Hamburg.	15,000	65,000	4	Steam turbines Blohm & Voss.	240
"George Washington"	25,570	17	U.S. Shipping Board	1908	600.1 x 78.3 x 50.1	A. G. Vulcan, Stettin.	13,465	18,000	2	Reciprocating A. G. Vulcan, Stettin.	215
"Adamson" (ex "Kaiser Wilhelm II.")	19,301	21½	U.S. Shipping Board	1902	684.5 x 72.3 x 40.2	A. G. Vulcan, Stettin.	8,700	43,000	2	Reciprocating A. G. Vulcan, Stettin.	213
"Panama State"	10,513	14	U.S. Shipping Board	1920	402.1 x 62.2 x 28.3	New York S. B. Corp.	13,000	7,000	2	Reciprocating New York S. B. Corp.	220
"France"	23,666	24	Cie. Gen. Transatlantique	1912	689.0 x 75.6 x 51.4	Ch. & Atel. de St. Nazaire, St. Nazaire.	6,184	45,000	4	Steam turbines Ch. & Atel. de St. Nazaire.
"Paris"	39,000	22	Cie. Gen. Transatlantique	1917	734.9 x 85.2 x 59.1	Ch. & Atel. de St. Nazaire, St. Nazaire.	4	Steam turbines Chant. de Penhret, St. N.
"Mauilla"	15,147	20	Cie. de Nav. Sud-Atlantique.	1916	574.0 x 64.0 x 40.2	Forg. & Ch. de la Médit., La Seyne.	4	Reciprocating & s.l.p. turbines Forg. & Ch. de la Médit., M.S.L.
"Rotterdam"	24,149	17	Holland-America Line	1908	650.5 x 77.4 x 43.5	Harland & Wolff, Belfast.	2,451 N.H.P.	2	Reciprocating Harland & Wolff, Belfast.	215
"Limburgia"	10,980	17	Koninkl.-Hollandsche Lloyd	1914	502.0 x 72.3 x 39.7	J. C. Teeklenborg, A. G., Geestmünde.	3	Reciprocating & l.p. turbine J. C. Teeklenborg, A. G., Geest.
"Giulio Cesare"	21,500	18½	Nav. Gen. Italiana	1920	601.4 x 76.0 x 51.0	Swan Hunter, Newcastle.	4	Steam turbines Wallsend Slipway Co. Ltd., Newcastle.
"Conte Rosso"	15,550	Lloyd Sabaudo Socy.	1921	570.0 x 74.3 x 36.2	Beardmore, Glasgow.	2	Steam turbines W. Beardmore, Glasgow.
"Esperia"	11,393	20	Soc. Italiana di Servizi Marittimi	1918	492.1 x 61.7 x 34.1	Soc. Esercizio Bacini Riva Trigono.	19,600 H.P.	2	Geared steam turbines N. O. dero de A. Scutoli, P.
"Infanta Isabel de Borbon"	10,348	Cia. Transatlantica	1913	481.0 x 61.3 x 32.7	W. Denny Bros., Dumbarton.	6,220	22,186	3	Reciprocating & l.p. turbine Denny & Co., Dumbarton.	200
"Stavengerfjord"	12,977	15½	Den Norske Amerika Linje	1918	532.5 x 64.2 x 30.3	Cammell Laird & Co., Birkenhead.	7,200	1,567 N.H.P.	2	Reciprocating Cammell Laird & Co.	220
"Bergensfjord"	10,700	Den Norske Amerika Linje	1913	512.4 x 61.2 x 29.4	Cammell Laird & Co., Birkenhead.	7,300	1,460 N.H.P.	2	Reciprocating Cammell Laird & Co.	220
"Campania" (lost in World War).	19,884	22	Cunard Co.	1893	601.0 x 65.2 x 37.8	Fairfield Co. Ltd., Glasgow.	1,191 N.H.P.	2	Reciprocating Fairfield Co. Ltd., Glasgow.	165
"Great Eastern"	18,015	13	Great Eastern S.S. Co.	1858	690.0 x 82.8 x 48.2	Millwall.	11,000 I.H.P.	S. screw & paddles.	30

The U.S. Shipping Board has allotted many of its best vessels to various companies for service on the Pacific. The "Wenatchee" and "Creole State" are typical of the 535-ft. vessels so appropriated. These vessels are 535 ft. overall, 516 ft. between perpendiculars, with a beam of 72 ft., and moulded depth 27.8 ft., and to "A" deck 50 ft.; about 14,000 tons gross. When loaded to a draught of 0.6 ft. their total dead-weight is 10,000 tons, and total displacement 21,250 tons. They have accommodation for 257 first-class and 300 second-class passengers, besides 200 of ship's company. They can also carry 6,700 tons of cargo, and can maintain 17½ knots for long distances, having obtained over 19 knots in some cases on trial. They are fitted with water-tube boilers 265 lb., and 5" superheat. Westinghouse double-flow type turbines are fitted, run at 3,650 revolutions, with double reduction gearing, to drive two propellers at 110 revolutions. The smaller vessels of the same type are 522 ft. overall, 502 ft. between perpendiculars; breadth 72 ft. and depth to "A" deck 42 ft. They only carry 78 passengers, but they can take another 1,000 tons of cargo. They are fitted with cylindrical boilers 220 lb., and two sets of four-cylinder triple expansion engines giving 6,000 H.P. for 14 knots at 105 revolutions.

For service between Europe and Australia, via The Cape, the "Ceramic," of 18,481 tons and 17 knots, triple screw, of the White Star line, was the finest and largest vessel running in 1921. She was built by Harland & Wolff in 1913, and can carry 19,590 tons cargo, and bunkers, at a sea speed of 17 knots, with a maximum of 18½ knots. For the India and Australia service of the P. & O., a new series of "N" class of steamers was being built. The first of these "Nalders," 15,825 tons, was built by Caird, and used by the Government during the war. "Narkunda," 16,118 tons, was the first liner to be completed by Harland & Wolff at Belfast after the war. These are vessels of 18½ knots speed. For the India service direct a new series—"M" class—was being built. Typical of these is the "Mongolia," built by Armstrong, 550 ft. x 72 ft. x 42.3 ft. When loaded to a draught of 30 ft. they will have a displacement of 24,500 tons, and 15,550 tons gross, and carry a dead-weight of about 13,000 tons. They can carry over 400 first- and second-class passengers, and of seven cargo-holds two are insulated. Two later vessels—"Maloja" and "Mooltan"—are 20,700 tons gross.

The Cunard Co. has also built a number of vessels of the "Ausonia" type for the Cape and Australia services. These vessels are 519 ft. x 65.3 ft. x 43 ft., and 13,000 tons gross at a draught of 29.6 feet. Their displacement is 20,420 tons with a dead-weight of 10,120. Geared turbines of 8,500 H.P. are fitted for a speed of 15 knots. They can carry over 500 cabin passengers and about 1,200 third-class. The "Ausonia" is remarkable, as making a record of 1,000 ships built by Messrs. Armstrong, of a total of 3,000,000 tons. Of these, 800 were merchant ships and 200 were warships.

The Australian Government was in 1921 providing itself with seven liners of 12,500 tons, 15 knots full speed, built on the Isherwood longitudinal system. The "Larga Bay," built by Messrs. Beardmore, may be taken as typical of all five. She is 530 ft. long, breadth 68.3 ft., depth 39.8 ft., 12,500 tons gross tonnage, and can carry 12,000 tons dead-weight at a draught of 29 ft. 9 in. and displacement 23,120 tons. She can carry 730 third-class and about a dozen first-class passengers. Machinery, of 9,000 S.H.P. on two shafts, is provided for a speed of 15 knots; Parsons' geared turbines are fitted in two complete sets. The h.p. turbines run at 3,200 revolutions, and l.p. turbines at 2,100. They are independently connected to the shafts by double reduction gearing 35.5 to 1, and 23.4 to 1 respectively, giving a speed of propellers of 90 revolutions per minute, and on each ship astern turbines are provided equal to 60 to 65% of the full power ahead.

South Africa.—For the direct service to the Cape the Union Castle line added the "Balmoral Castle," of 13,361 tons, of 18 knots maximum speed, in 1911. Two very fine vessels had in 1921 been recently added: the "Arundel Castle," and "Windor Castle," 650 ft. x 72 ft., and of 19,000 tons gross. They were the first four-funnelled ships on the Cape line, and were fitted with 15,000 H.P., and single reduction gear, to two shafts, for a sea speed of 17 knots. They could carry 273 first-, 224 second- and 506 third-class passengers, besides the crew of 400, and a large cargo, the total dead-weight being 14,000 tons.

Coast and Channel Steamers, etc.—The finest recent vessels of these types have been built in America. Two remarkable vessels, the "Great Northern" and "Northern Pacific," built by Cramp in 1915 for service between San Francisco and Astoria, are 8,255 tons gross and 24 knots speed. They are 500 ft. x 63 ft. x 50.5 ft., moulded, to promenade deck. When loaded to 21-ft. draught they have dead-weight of 2,185 tons and displacement of 9,700. They carry 550 first-class passengers and 316 second and third-class passengers. They are fitted with 12 water tube boilers of the Mosher type, and Parsons turbines driving three screws, and giving 22,000 S.H.P. These were, perhaps, the finest vessels that had yet been built in the United States, though not the largest.

New Channel steamers have continued to be built in England, France and Belgium. The fastest steamer on the English Channel service in 1921 was the "Versailles," built in France and completed in 1921, 305 ft. long and 36 ft. in breadth; she had obtained 25 knots on speed.

An important type of cross-channel steamer is the train ferry. During the war such vessels were used by England for the first time. These vessels are 363.5 ft. long, 61.5 ft. broad, draught 9 ft. forward and 10 ft. aft. They displace 3,654 tons, and have 12 knots speed. Two were built by Messrs. Armstrong and one by Messrs. Fair-

field. On the deck, well protected by deckhouses, are four lines of rails, which will take 54 10-ton wagons. Heavy guns and heavy machinery of all description were transported by these vessels.

Some of the most remarkable vessels in the world are the Sound and Lake steamers of the United States. Recent vessels on the Lakes are the largest paddle steamers ever built, such as the "City of Cleveland III." (1907), 4,568 tons and 19 knots speed; "City of Detroit III." (1912), 6,061 tons and 20 knots speed; and "Seand-bee" (1912), 6,381 tons, 19½ knots. This last remarkable vessel is 484.5 ft. x 58.1 ft. x 24.0 ft. To drive her paddle wheels she is fitted with compound, three cylinder engines; cylinders being, one 66 in. in diameter, and two 96 in. in diameter, with a stroke of 9 feet.

Developments in Shipbuilding.—The greatest innovations during 1910-20 were in connexion with rapid shipbuilding during the war. The production of "standard ships" in Great Britain has been already referred to. Six types were "standardized" (see Carter I.N.A., 1918, and, for detailed summary with dimensions, *Ship-builder*, May 1918).

Others were approved at a later date, and permission to build large numbers of such ships was given to various shipbuilders. In these ships special methods were adopted to reduce risk of submarine attack, such as improved sub-division, making both ends alike, with bridge, poop and fore-castle ends rounded, funnels and masts symmetrical in profile elevation with regard to a vertical line amidships, but not on the fore and aft centre line so as to increase difficulty of detecting speed and course of vessel. Very greatly improved accommodation for ship's company was also provided.

The best method of expediting the building of merchant ships occupied many minds, and proposals were made by Sir Eustace d'Eyncourt in 1917 to simplify the construction of war-time vessels by making all frame-lines straight, and the plating so far as practicable of developable surfaces. A successful design was proposed on this basis, and adopted by the Controller of Merchant Shipbuilding for use in the fabricated ships about to be built at the National Shipyards on the Severn. The first fabricated "straight line ship," the S.S. "War Climax," was completed at Wallsend by Swan, Hunter & Co., on Sept. 28 1918, 31 weeks from laying keel.

In Great Britain large numbers of vessels of standard designs were built by various shipbuilders according to their usual routine. The "fabricated" ship followed later. In the United States, however, the standard ships were mostly fabricated ships also. The first series were produced by the Submarine Boat Corporation in new premises at Newark Bay. The most wonderful of all the American shipyards was, however, at Hog's I., Philadelphia, which in less than 12 months passed from open 50 ft. ground to the greatest shipyard in the world, with full equipment and deep water jetties. The contract was signed on Sept. 13 1917, and work started Sept. 20. The first keel (S.S. "Quistconck") was laid Feb. 12 1918, launched Aug. 5 1918, and by Jan. 8 1919, 16 vessels had been launched and 7 completed, 50 ships had been built and 7 jetties, 1,000 ft. long and 100 ft. wide for fitting out afloat. By April 17 1920, 102 ships of 800,000 tons d.w. had been launched and 84 of 657,000 tons completed. The fabricated parts were prepared in 90 engineering works from 10 to 1,500 m. away.

Ferro-Concrete Ships.—For many years small vessels had been built of reinforced concrete in localities where steel and the special labour required for steel shipbuilding was not available. Such vessels had been built in Italy, Norway and France. Between 1887 and 1917 some 200 craft had been built, but in the latter year the subject was more seriously considered, and craft of increasing size were built, and greater numbers of them fitted with propelling machinery. In England 1,000 ton barges, tugs of 750 h.p., and cargo steamers of 1,150 tons d.w. were built. The first steamship, "Armistice," was built at Barrow, and was reported to run well and cost very much less than a steel ship for upkeep. In Great Britain most of the concrete vessels were tow barges, but in a number of cases steam or oil engines were fitted. Cargo boats 1,150 tons d.w. 205 ft. x 32 ft. with engines of 350 I.H.P. for 7½ knots, and tugs 125 ft. x 27 ft. 6 in. with engines of 750 I.H.P. were built. In the United States very much larger vessels were built as experience was gained. The S.S. "Faith" was 320 ft. x 44.5 ft. x 30 ft. d.w. 3,950 tons on 22 ft. 6 in. draught, triple expansion engine of 1,600 I.H.P. were fitted giving 10½ knots speed. Others were built of 3,000, 3,500 and 7,500 tons d.w. as well as eight oil tankers of 7,500 d.w. The Emergency Fleet Corporation ordered 56 ships of an aggregate d.w. of 300,000 tons, besides 34 barges and lighters.

Welded Ships.—The Oxy-Acetylene process, for cutting out damaged portions of ships and machinery, and for welding in portions in the course of repair, has been of great service, particularly for the repairs of large forgings, castings and boilers. To a less extent the "Thermit" process has been used for welding purposes, but its application has been of a comparatively limited character. During recent years very considerable progress has been made in developing systems of electric welding, which were used to carry out repair work of considerable magnitude during the war. It has also been proposed that the complete ship should be welded, thus avoiding a great portion of the labour and expense of riveting. Several systems have been developed which can be operated in the ordinary shipyard, and considerable progress has been made in Sweden, England, the United States and France. In 1915 a small vessel

was built by Geary at Ashtabula Harbour, Ohio. This vessel was 42 ft. long, 11 ft. beam and 6 ft. 6 in. draught, and the welding was carried out with bare metallic electrodes. Two vessels of 52 to 62 ft. in length have also been built, one in France in 1919 and one in 1920 in Sweden "Esab IV." In each case the welding was carried out by the Kjellberg process, and each of these craft is propelled by semi-Diesel crude oil engines, which can also be used to provide electric power for welding, and compressed air for use in carrying out the repairs of ships by this process as they float in harbour. In this process the arc is also used, but a fireproof sleeve of non-conducting material projects over the arc so as to shield the molten metal from oxidization. A boiler 15 ft. 6 in. in diameter, known as the Hawthorn-Wyber boiler, has been successfully constructed by means of this process. The process of the General Electric Co. is quite different; in this case metallic contact takes place, the welding material is raised to the necessary temperature by resistance to the passage of the current, and it is at the same time pressed into place by hydraulic pressure. A 46-ft. section of a 9,500 ton vessel being built in New Jersey has been used to test the practicability of this, and other methods, and it is reported that these experiments show a saving of 60% on labour and 15% on material, as compared with riveted work.

During the war a steel barge, 120 ft. by 16 ft. and 275 tons displacement, was built at Richborough, Kent, in order to test to what extent labour could be saved. Here the Quasi-Arc process was used and the vessel was satisfactorily completed. On this system the steel electrode has a sheath of blue asbestos, which melts and flows down over the molten metal, thereby extinguishing the arc. This asbestos also forms a floating covering over the molten metal and protects it from oxidization. In order to give further protection, an aluminium wire is carried down by the side of the steel electrode, so that the molten aluminium may take up any oxygen which gets beneath the flux. Messrs. Laird built a small sea-going vessel, the S.S. "Fullagar," in 1920, using the Quasi-Arc process. If welding can be adopted as the general practice, a very large saving should arise in the cost of labour, and an appreciable saving in the case of weight and material.

FIG. 50.

Isherwood System.—For many years warships have been built on the longitudinal system of framing, i.e. the principal structural members of the framing run fore and aft in continuous girders, the transverse framing being of a secondary character (apart from bulkheads), and fitted between the longitudinal girders as necessary for local support. This system of framing has not found general acceptance for merchant ships, because of the theory long held by ship-owners that a merchant ship must have such strong transverse frames that she may ground in an ordinary berth with a cargo on board and without damage. With the improved wharf accommodation now available for important vessels this idea is being gradually relinquished. The most important movement in this connexion was inaugurated by Mr. (later Sir) Joseph Isherwood, who devised a plan for utilizing the whole of the framing of the bottom of the ship and of the decks so that it might be incorporated as part of the structural girder strength of the ship. In 1908, six ships were built of 31,000 tons; for the next six years, 40 or 50 ships were built per annum; but in 1915, under war conditions, the number very greatly increased, and in 1918, 250 ships of nearly 2,500,000 tons dead-weight capacity were built. Clearer holds, greater strength and a saving of about 10% of weight of structure are obtained, as well as decreased cost of building. By June 1921 1,400 ships, aggregating 12,000,000 dead-weight, had been built on this system.

The combination of a longitudinal system in the double bottom, and a transverse system above the bottom, has been adopted by Mr. W. Millar of Greenock, and several vessels have been built on the Millar system. Other systems in which a longitudinal construc-

tion is adopted are associated with various names—Mr. Foster King, Dr. Montgomery, and Sir Westcott Abell.

The "Unsinkable" Ship.—A so-called "unsinkable" ship has been designed by M. La Parmentier. It consists of two cylinders, 22 ft. in diameter and about 300 ft. in length, each divided into 7 holds, connected so as to form a vessel 320 ft. in length and about 48 ft. extreme breadth, estimated to carry 4,250 tons d.w. on a draught of 16 ft. fitted with twin screws, and engines of 700 H.P. for eight knots. In 1921 several such vessels were being built in the United States.

Cruiser Sterns.—Several of the new liners have a rounded stern, with the profile sloping forward in a curved line as it rises from the water upwards. This is called a "cruiser stern," and is being very generally adopted. It gives somewhat increased capacity, and with the same total length of ship provides a longer water-line, thus facilitating propulsion. In the case of a 550-ft. ship, for 18 knots this meant a decrease of 2,000 H.P., which resulted in a saving of 225 tons of machinery, as well as 220 tons of fuel per trip, giving a saving of over 400 tons available for extra cargo. In 1921 over 160 vessels were built with sterns formed in this way.

On this system the flat plate rudder is replaced by two curved plate rudders ("Kitchen rudders"), forming an almost cylindrical casing round the propeller. By revolving these curved rudders as desired the stream of water is directed as necessary by reaction to steer the ship. For going astern the rudders are brought together abaft the propeller.

Safety at Sea.—During the war many other points were developed for increase of safety in navigation, such as use of range-finders, directional wireless, gyro-compasses, reflex sound apparatus, "clear view" weather screens, submarine sound signalling, and "Leader" cables laid along the bed of the channel.

Following the loss of the "Titanic" on April 16 1912, rigorous enquiries were conducted, in New York under Senator W. A. Smith of Michigan, and in London under Lord Mersey. In both cases recommendations were made that liners should have boats for all, regular boat drill, more efficient W.T. arrangements, and improved sub-division in construction. The British Board of Trade appointed two committees. Sir Archibald Denny presided over the first committee (Bulkheads and Sub-Division) and Sir John Biles over the second committee (Boats and Davits). As a result the Board of Trade laid draft rules before Parliament (Paper Cd. 6402 1912) and took immediate action to improve the supply of boats, while shipowners proceeded to improve the sub-division of their ships. An International Convention was called with a view to similar treatment of these questions by all maritime powers. This Convention was signed on Jan. 20 1914 and rules embodying the agreement as to life-saving appliances were immediately put into force in Great Britain (Parliamentary Paper 219 Merchant Shipping Life-Saving Appliances dated May 8 1914). The whole Convention was discussed in Parliament, and an Act was passed (Aug. 10 1914) authorizing its adoption, but the Board of Trade was left with the power to decide the date on which the Act was to be put into operation. On account of the war, action was postponed, but discussions were proceeding in 1921 between the principal maritime powers with a view to the holding of another Convention.

During the war a great demand arose for improved life-saving appliances. The most successful of all these was the Carley Life Raft, made in the United States. It is made in various sizes. A large copper pipe is bent into the form of an O, brazed up to be airtight, surrounded by cork and canvas, provided with a strong rope netting to form a floor within the O, and fitted with hand ropes, etc. This type was the means of saving very many lives; for instance, a float 9 ft. by 14 ft. will support more than 60 people.

Research and Experiment.—Increasing attention is being given to the study of naval architecture and marine engineering, and of research, in America as well as in Europe. Chiefly owing to the advocacy of Sir W. H. White, and the generosity of Sir A. F. Yarrow, a national experimental tank has, in England, been provided at the National Physical Laboratory at Teddington. The experiment tank is intended for the service of any shipbuilding or shipowning firm. Primarily intended for the experimental investigation of any problems connected with ship resistance and propulsion, it has successfully dealt with such different problems as the manœuvring of ships, torques on rudder heads, skin friction, resistance due to rough seas, rolling and pitching of ships, stability of ships and hydroplanes in motion on the water, and the form of flying-boat hulls for efficient and stable action in getting on and off the water. During the war it dealt with many problems, including the detection of submarines, mine-sweeping, torpedo firing, design of anchored mines, protection against torpedoes, and the design of standard ships. (E. T. D'E.)

SHIPPING (see 24.983).—In the decade following 1910, the influence of the World War had a profound effect on the shipping industry. Nor can it be limited to the period between the beginning of Aug. 1914 and Nov. 1918, when the Armistice was signed. For many months after the cessation of hostilities, a great strain was imposed on the British mercantile marine in the repatriation of millions of men. Goods which could not be trans-

ported during the war were waiting in vast accumulations to be carried, and in 1921 the effects on shipping were still being shown. In fact, so far-reaching were the effects that they were certain to be felt for many years.

(1) UNITED KINGDOM

The year 1910 was, judged by the ideas then ruling, a comparatively satisfactory one for British shipping, although the industry did not entirely escape the consequences of a strike of coal-miners caused by difficulties traceable to the operation of the Eight Hours Act. In 1911 there were a number of industrial disturbances, notably in the collieries, on the railways, at the docks, among seamen and in the cotton-mills. Yet rates of freight were on a higher basis than for some years previously. The time charter rate, i.e. the monthly rate of hire per ton dead-weight for ordinary cargo steamers, may be taken as a good barometer of the condition of freight rates generally. As compared with a rate of about 3s. a ton, or rather more, ruling in 1910, the time charter rate rose to about 5s. in 1911. There was a further upward movement in 1912, which was regarded as a very satisfactory year for the shipping industry. Time charter rates ranged from about 4s. 6d. a ton to 7s. 6d. Employment for shipping was good, although, as some set-off to the increased rates, there was a general rise in working costs. In 1913 rates declined, partly owing to the increase in shipbuilding which had been carried out during the good years. The year 1914, destined to be one of the most important for shipping as for all other industries, opened with freights on a downward grade, and in mid-summer the industry was in a very depressed condition. All freight rates for cargo steamers were low, and the liner companies were feeling the severe competition of the German ownerships. The two great German companies in the N. Atlantic trade—the Hamburg-Amerika and the Norddeutscher Lloyd—had been for years claiming a larger share of the passenger traffic. In the summer of 1914 the Deutsche-Australische Gesellschaft announced its intention of inaugurating a direct service from Hamburg to New Zealand. Discussions were in progress with the British shipping managers when war broke out.

Beginning of the World War.—Immediately a number of liners were requisitioned by the British Government for service as merchant cruisers, transports, and hospital ships. Freight markets were almost staggered by the unexpected blow which had fallen, and, at first, chartering of all sorts came to a standstill. Happily, the Government at once put into operation a scheme of war insurance on the lines of the recommendations of a committee which had been previously appointed and was presided over by Mr. Huth Jackson. These recommendations provided for the granting of war insurance on shipping by the Government up to 80% of the values. This insurance was worked through the mutual associations of shipowners which were in existence for the purpose of covering such liabilities as shipowners could not obtain under ordinary marine insurance policies. In the preparation of this scheme Sir Norman Hill, the secretary of the Liverpool Steamship Owners' Assn., had taken an active part. The shipping entered in the Liverpool Steamship Owners' Assn. represented 3,948,623 tons, and that in the Liverpool and London War Risks Assn., which included the great bulk of the liner tonnage of the United Kingdom, 6,371,320 tons.

There were also important associations of the same kind with headquarters in London and on the N.E. coast. The main result of putting this scheme at once into operation was that all ships could proceed on their voyages and others could leave without involving disaster to their owners if the vessels were captured or destroyed by the enemy. Had no such scheme been available, a great many vessels, if not all, must have been detained in port. Commerce would immediately have come to a stop. In those days it was the possibility of capture by the enemy's surface cruisers that was in men's minds: that was considered serious enough. The risk of destruction by the enemy's submarines had hardly been taken into account.

As a complement to this scheme for the insurance of hulls, there was also established a Government office for the insurance

of cargo. The marine insurance market continued actively in business, but underwriters had themselves realized that had news or heavy losses could easily have the result of forcing up rates to levels that might be prohibitive for commerce. The Government office was intended to exercise a steadying influence. It was vital that essential goods should continue to be shipped, and, if the risks were greater than insurance companies or private underwriters could bear, it was for the nation to assume them. The first rate quoted by the Government was £5 5s. %. On Aug. 8 the rate was reduced to £4 4s., on Aug. 18 to £3 3s., and on Sept. 2 to £2 2s.

All the time underwriters in the market continued to write war risks. Their rates of premium were frequently below those of the Government, and there were many risks which the Government office would not accept. For instance, the Government office would not accept lines after a ship had left port. Merchants sometimes found that larger quantities of goods had been shipped than they had anticipated, or that the values were greater. Then insurances were effected in the open market. As Germany was no respecter of the rights of neutrals, insurances were also placed in the market on behalf of steamship owners abroad. Some underwriters of insurance companies and at Lloyd's wrote war risks freely from the outset. They took big risks and made large sums of money. The premium incomes of the insurance companies writing war risks were, in some cases, as much as five times the pre-war standard. This was due not only to the demand for insurance against war perils, but also to the great increase in values of commodities which set in as they became scarce.

The Government office was inaugurated under the auspices of the Board of Trade. The services of a number of leading underwriters were enlisted. On Aug. 5 1914, the office was opened at the Cannon Street hotel and the knowledge that there was a market for the risks undoubtedly had a very reassuring effect. While credit was due to several underwriters who gave their services in the working of this scheme, much of the organization fell upon Mr. W. E. Hargreaves, a leading member of Lloyd's, who worked in close co-operation with the Board of Trade.

There were thus in existence from the very beginning of the war facilities for the insurance of ships and cargoes against all the perils that then had to be faced. There was not the same mobilization of the shipping industry.

Immediately after the declaration of war, freights remained listless. A very few shipowners were able to see what was coming, and chartered neutral steamers for "time" at the low rates then ruling, and, in the event, found the transactions very profitable. Most shipowners, however, did not foresee the extremely heavy demands which would be made by the Government upon the industry for ships for direct war purposes. Cargo steamers were requisitioned to act as colliers to the fleet and were needed to carry supplies to the armies abroad. It was not until the end of 1914 that freight rates began to move upwards. Just before the outbreak of war the grain rate from Argentina which may be regarded as a representative rate, was 12s. 6d. per ton. By the end of the year this freight had advanced to 50s. per ton. It rose again sharply in the autumn of 1915, and its movements indicated the influence of the introduction of the Excess Profits duty. On Sept. 20 of that year, when Mr. McKenna, the then Chancellor of the Exchequer, introduced the tax, the Argentine grain freight stood at 57s. 6d. per ton. Within a month it had risen to 70s., by Nov. 20 it had advanced to 85s., and by Dec. 20 to 120s. In 1916 the rate advanced further. By Jan. 20 of that year it stood at 140s. and by Feb. 20 at 157s. 6d. The rate further advanced in 1916 to 183s. 6d. Similar increases took place in other shipping trades. These increases were clearly due, in the first place, to the diminution in the supply of shipping available for commerce, which, in turn, was caused by the ever-increasing requirements of the Government, and by the destruction of shipping by the enemy, and also to the incidence of the Excess Profits duty. This tax provided the argument that the nation got the benefit of the increases. The Treasury did, but not the country which had to pay for them in the increased cost of imported commodities. It represented a form of taxation, at

the best, imposed without the authority of Parliament, and the surplus remaining to the owners meant higher profits than, in pre-war years, could ever have been thought possible by them.

For nearly two and a half years the real responsibility for the shipping not requisitioned by the Admiralty rested with the Board of Trade, of which Mr. Walter Runciman was then President. The President of the Board of Trade, with his multitudinous duties of endeavouring to watch over the welfare of all industries, was obviously incapable of giving the close attention to shipping which all the circumstances demanded. The public gradually became keenly interested in the rise that was proceeding in freights and was irritated by it. As its interest developed, it grew into indignation. The matter was raised in Parliament, but the Government of the day showed complacency, regarding the movement apparently as inevitable. It is true that on Christmas Eve, 1915, when freights were still climbing, Mr. Arthur Balfour referred in the House of Commons to the "terrible level" of freights which, he admitted, increased the price, both of the necessities of life to the poor, and of many things which were essential to the Government in the proper conduct of the war. Yet the Government, when it was spurred into action, contented itself with adopting further piecemeal measures.

Government Measures.—One successful measure taken at the outset might have formed a model for a broader policy, and, two and a half years later, did so. This was the requisitioning by the Government of the whole of the refrigerated space in the meat steamers trading between the United Kingdom and Australasia. This transaction was followed, a few weeks afterwards, by the requisitioning of similar space in the steamers trading with S. America. Arrangements were, at the same time, concluded by the Government with the meat companies for a proportion of their weekly production at fixed prices. Thus, not only were there ample supplies secured for the navy and army at reasonable cost, but supplies were available to maintain the civil population.

In the autumn of 1914 owners were asked to keep the Admiralty informed of the movements of their ships. It was a peculiar fact that very little, if any, information was then in the hands of any Government department of the services of the British shipping companies. Such information had to be sought from the companies themselves.

In the summer of 1916 a scheme was instituted, on behalf of the Indian Government, for buying in India, transporting to the United Kingdom and selling there the exportable surplus of the Indian wheat crop and, through the formation of a committee of brokers, the freight rates were kept on a comparatively moderate basis. In the autumn of that year the Imperial Government was forced into further action. A committee was appointed to consider the desirability of particular voyages and a system of licences was introduced. Another committee was formed for the requisitioning of vessels for the transport of foodstuffs, and a third, known as the Port and Transit Executive Committee, was formed to deal with the congestion at the ports of the United Kingdom, which, by then, had become a very serious matter. As from March 1 1916, licenses were required for all ships of over 500 tons gross trading to and from the United Kingdom.

Licences were granted for whole services or particular voyages. The system also enabled discrimination to be exercised between the different ports of the United Kingdom and so it was important in the relief of congestion.

The committee appointed to deal with the requisitioning of ships for foodstuffs followed the policy of directing owners to load their vessels where the need was most urgent and then to leave the owners to accept the full market rates of freight.

The first chairman of the Port and Transit Executive Committee was Lord Inchcape, and the Committee included representatives of the Admiralty, the War Office, shipping, railways and dock authorities. It was subsequently strengthened by the addition of Labour leaders. It owed responsibility, directly, to the Prime Minister and adopted such measures as would tend to relieve congestion at the ports. Its task was a formidable one and, while the Committee was able to bring about certain reforms, it could not entirely remove the troubles. These actually seemed to be

at their worst after the Armistice. Immense supplies of commodities which could not be moved during the war were poured into the country, and the facilities for removing these proved quite inadequate, with the result that ships were detained for long periods, owing to inability to discharge their cargoes. Much public attention was focussed on the waste of shipping thereby involved. Strenuous efforts were made by all concerned to improve the situation. As an indication of what was being done, the Port of London Authority issued a weekly bulletin showing the number of vessels detained, and continued to issue this until the situation was completely changed and, early in 1921, the weekly return showed that large numbers of steamers were laid up idle owing to the lack of employment. Lord Inchcape was succeeded as Chairman of the Committee by Sir Norman Hill, who, on a breakdown of health caused by overwork was, in turn, succeeded at the end of 1919 by Sir John Barran. The Committee was formally dissolved by the Prime Minister early in 1921. During the period of its activity it had wide powers, and, at the outset, had, among other measures, effected a change in the Customs Regulations which, as was proved, were then having the effect of accentuating the difficulties.

The chairman of the Ship Licensing Committee was Mr. (afterwards Sir) Maurice Hill, and it included Mr. (afterwards Sir) F. W. Lewis, then deputy chairman of Messrs. Furness, Withy & Co., as vice-chairman, Mr. H. A. Sanderson (president of the International Mercantile Marine Co. and chairman of the Oceanic Steam Navigation Co.), Mr. Scholefield, of Newcastle, Mr. Purdie, of Glasgow, and Mr. Burton Chadwick, of Liverpool.

The Committee for the requisitioning of ships was presided over by Mr. J. H. Whitley, who in April 1921 became Speaker of the House of Commons. It included three shipowners, namely, Mr. (afterwards Sir) T. Royden, deputy chairman of the Cunard Co., Mr. (afterwards Sir) E. W. Glover, of the shipowning firm of Glover Bros., and Mr. R. D. Holt, the chief of the important shipowning firm of Liverpool. All these members had previously been advising the Transport Department of the Admiralty.

In spite of the measures that were being adopted, freights remained on a very high level, and the shipping situation was very unsatisfactory. The need for complete control was urged persistently in *The Times* newspaper, and in Feb. 1916 the Government was again forced to act. In that month an Allocation Committee, or Shipping Control Committee, was formed in order to apportion the tonnage according to the various and urgent demands that were made upon it. Lord Curzon was appointed chairman of this Committee. Other members were Lord Faringdon, then better known as Sir Alexander Henderson, Mr. Thomas Royden, and Mr. F. W. Lewis.

Supply of Tonnage.—It became plainer every day that the ever-reducing supply of tonnage was becoming less adequate to meet all the demands made upon it. Consequently, the Government decided to place restrictions on the importation of various commodities. The first of these to be effected were paper, paper-making materials, tobacco, dried fruits, furniture woods, stones and slates. In March 1916, a prohibition was placed on the importation of many articles under the general heading of "luxuries." Among such articles were motor-cars for private use, musical instruments, cutlery, hardware, cotton and woollen manufactures, chinaware, fancy goods and soap. A restriction was also placed on the importation of certain brewing materials.

The inadequacy of the tonnage to meet the supplies was at that time due more to the requirements of the Government for ships for direct war purposes than to the depredations of the enemy. The highest quarterly loss of British shipping due to the enemy was 356,000 tons in the third quarter of 1915. In 1916 the ratio of loss fell; in the second quarter, the total amounted to 271,000 tons and in the third quarter to 284,000 tons. This drop was, however, only temporary, and in the fourth quarter of 1916 the total sprang up sharply to 617,000 tons and then continued at a high rate until the conclusion of the Armistice.

Throughout 1916 what became known as the "shipping problem" continued to attract great public attention. Articles were published in *The Times* urging the need of centralized control, in

order that the utmost use might be made of the continually declining supply of tonnage and so that ships might be employed in the most effective way, irrespective of the individual trades of the ownerships to which they belonged. It was realized that this could only be brought about when all ships were hired to the Government, so that it would become for the owners a matter of more or less inconsequence into which routes the vessels were put. The principle of standardization was also persistently urged in order that large numbers of vessels might be constructed on identical plans and of parts fabricated from the same models. It was not, however, until the formation of Mr. Lloyd George's Government in Dec. 1916 that the shipping situation was completely taken in hand.

Ministry of Shipping.—A feature of the new Government was the creation of a Ministry of Shipping. As Shipping Controller, Sir Joseph Maclay was appointed. Sir Joseph Maclay had been known in shipping circles as a successful manager of cargo steamers and, while he was little known to the general public, the appointment was regarded in the shipping industry as a good one. By his own wish Sir Joseph Maclay was not a member of the House of Commons, but was represented there by Sir Leo Chiozza Money, as parliamentary secretary.

Various measures were soon taken to secure a better grip of the shipping problem. One of the most important of these was a general requisitioning of liners by the Government. These vessels were hired to the Government on the basis of what were known as Blue-book terms—those agreed early in the war with the Admiralty by a committee of owners presided over by Lord Inchcape. The management of such vessels as could be retained in ordinary commerce was left with the owners, who were required to give a financial account of their stewardship to the Government, and to pay over all profits above the Government rates of hire. Under this system it was less important to the individual ownerships into which routes their vessels were put. It was well that control was centralized, for, early in 1917, the enemy submarine war intensified and the losses greatly increased. As compared with a loss of 617,000 tons in the last quarter of 1916, the British tonnages sunk in the first quarter of 1917 amounted to 912,000 tons. The pinnacle was reached in April of that year and for the second quarter of 1917 the losses totalled 1,362,000 tons. Sinkings of foreign vessels were proceeding apace all the time, and in the second quarter of 1917 the total losses for the world amounted to 2,237,000 tons. The losses for each quarter throughout the war period are shown in the following table extracted from a White Paper (C.9221) issued at the end of 1918:—

Period	British	Foreign	Total of
	Gross tons	Gross tons	Gross tons
1914			
Aug. and Sept.	341,824	85,947	427,771 ¹
4th Quarter	154,728	126,688	281,416

Totals	9,031,828	6,021,958	15,053,786

¹ This figure includes 210,653 gross tonnage interned in enemy ports. After Oct. 31 the tonnage lost by enemy action was: British 11,916, Foreign 2,159.

New Construction.—Attention was at once given by the Shipping Controller to the need of construction, and a programme for standardized ships was laid down. The principle of standardization had already received practical recognition in June 1916, when the Standard Shipbuilding Co., to operate at Chepstow on the river Wye, was formed. This company received very powerful support, the capital being subscribed by, among other companies, the P. & O. and British India, New Zealand Shipping, Orient Steam Navigation, Federal Steam Navigation, Messrs. Furness, Withy & Co., the Shire Line, Messrs. A. Weir & Co., Messrs. Harris & Dixon, Messrs. Trinder, Anderson & Co., Messrs. Bethell, Gwyn & Co., and Messrs. Birt, Potter & Hughes. Mr. James Caird, the head of Messrs. Turnbull, Martin & Co., was appointed chairman, and Mr. John Silley, managing director of R. & H. Green and Silley Weir, an old and famous shipbuilding firm, was appointed vice-chairman. In Aug. of that year this company acquired the engineering firm of Edward Finch & Co., Ltd., which had originally been formed to build Brunel's Bridge over the river Wye. In this yard three building slips were prepared, and at the beginning of 1916 two cargo steamers of 3,300 tons were being built there, in addition to a large number of smaller vessels. The first four slips for building steamers of up to 10,000 tons in the Standard Co.'s new yard were also being prepared. Difficulties had to be overcome in the way of securing sufficient labour and part of the scheme provided for the construction of a garden city. Early in 1917 much progress had been made with the provision of housing accommodation under licences from the Ministry of Munitions.

These yards were subsequently taken over by the Government. A great deal of money was spent upon them. Various difficulties arose, and the results of the work there were very disappointing. After the Armistice the great bulk of the property was sold to private interests.

On assuming office, Sir Joseph Maclay at once tackled the problem of shipbuilding, and appointed a committee to advise him on all matters connected with the acceleration of merchant ships under construction and nearing completion, and the general administration of a new merchant shipbuilding programme. This committee included Mr. (afterwards Sir) George J. Carter (of Messrs. Cammell, Laird & Co., Ltd.), president of the Shipbuilding Employers' Federation, as chairman; Mr. (afterwards Sir) W. S. Abell, (chief surveyor to Lloyd's Register of Shipping); Mr. (afterwards Sir) F. N. Henderson (of D. & W. Henderson & Co., Ltd.); Mr. James Marr (of J. L. Thompson & Sons, Ltd.); Mr. Summers Hunter (of the North-Eastern Marine Engineering Co., Ltd.); Mr. (afterwards Sir) C. J. O. Sanders (of the Marine Department, Board of Trade); and Mr. (afterwards Sir) W. Rowan Thomson (of Messrs. D. Rowan & Co., Ltd., president of the North-West (Clyde) Engineering Trades' Employers' Association); Mr. A. R. Duncan, secretary to the Shipbuilding Employers' Federation, who, as Sir Andrew Duncan was later appointed Coal Controller, was secretary to the new committee.

The last word in merchant shipbuilding then rested with the Admiralty, on the ground that it was necessary for the naval authorities to determine what proportion of labour and material should be allotted to naval and merchant construction respectively. These proportions were dependent on the view held as to whether it was better to concentrate on the building of destroyers and other craft for the destruction of enemy submarines and for the protection of merchant vessels, or to build merchant ships. There was a great deal to be said for the theory that it was better to prevent ships being sunk than to build vessels to replace those destroyed. In May 1917 Sir Eric Geddes was appointed to the post of Navy Controller, and shortly afterwards, Maj.-Gen. A. S. Collard, director of inland waterways and docks, in the department of the director-general of movements and railways, was appointed deputy controller for auxiliary shipbuilding. The latter term was used to cover all merchant vessels. In July 1917, Sir Edward Carson was succeeded as First Lord of the Admiralty by Sir Eric Geddes, and Mr. (afterwards Sir) Alan Anderson became Navy Controller. The problem of merchant shipbuilding was at this time acute. The British shipping destroyed by the

enemy in 1916 represented 1,498,000 tons, or nearly three times the production in British yards. This had fallen from the very poor total of 650,000 tons in 1915 to 541,000 tons in 1916. The peak in British shipbuilding had been reached in 1913, when 2,280,000 tons gross had been built, consisting of 1,920,000 tons of merchant vessels and 320,000 of warship tonnage calculated on a converted basis. It was to repeat such a production that the authorities at last aimed, the difficulties being enormously increased by the fact that large numbers of skilled men had been withdrawn from the shipbuilding industry for the fighting forces. The military authorities agreed to release such skilled men as could be spared, but as these were scattered over the various theatres of war, their return was very slow.

When responsibility for mercantile shipbuilding was transferred from the Ministry of Shipping to the Admiralty, some little friction arose between the new authorities responsible and the old Advisory Committee to the Shipping Controller, and in the autumn of 1918 a Shipbuilding Council to the Navy Controller was created, consisting of the members of the old Committee and advisers from the Admiralty. The position continued in some respects unsatisfactory, and in the spring of 1918, after an agitation for a more energetic merchant shipbuilding programme, Lord Pirrie was appointed Director-General of Merchant Shipbuilding, the official appointment being announced in the House of Commons on March 20 1918. He was regarded as the outstanding figure in British shipbuilding, and he was able to infuse energy into the shipbuilding programme. One of his first efforts was very greatly to improve the organization for the repair of damaged ships. Many vessels, after being torpedoed, managed to limp into ports, some of which, notably Falmouth, became seriously congested. A system of close and centralized control of the repairing facilities was organized, and much was done to make the damaged ships soon available again for service. The assistance of the United States in merchant construction had been earnestly invited. That country threw itself into the effort with immense fervour, and the height of the shipbuilding campaign was reached there in the summer of 1918. In June 1918, as responsibility for merchant shipbuilding now rested with the Department of the Controller-General, Sir. Alan Anderson resigned from the position of Navy Controller. After the Armistice the responsibility for the completion of the merchant shipbuilding programme was transferred again to Sir Joseph Maclay, the Shipping Controller.

Financial results of the shipbuilding programme were described in the House of Commons on March 12 1921, by Col. Leslie Wilson, parliamentary secretary to the Ministry of Shipping. Colonel Wilson stated that the total cost of 228 ships built in the United Kingdom for the Government was £36,481,000, and that the ships were subsequently sold for £47,591,000, showing a total profit of £11,110,000. An agreement was entered into with the Government by Lord Inchcape, who undertook to distribute the ships to those British owners who desired them, in proportion to their losses. The agreement was made on the basis that no profit should accrue to him through the transaction. Outside the United Kingdom there were built for the British Government 122 ships, the vessels being built at much higher prices than those paid for the vessels constructed in the United Kingdom. The total cost of these vessels was £26,884,000, and the selling price was £18,289,000, showing a loss on the ships built abroad of £8,595,000. The net profit on 378 ships built and sold, excluding any allowance for depreciation, was £2,515,000. Colonel Wilson maintained that the Government would have been fully justified in taking depreciation into account, and, allowing 5% depreciation on 311 ships which were being worked, there would have been a net profit not of £2,515,000, but of £5,122,000. Again, but for the new ships it would have been necessary for the Government to try to charter neutral vessels, for which high rates of freight would have had to be paid. This would, it was estimated, have involved an additional expenditure of £27,000,000. There was no question that the Government acted wisely, at any rate from the financial point of view, in disposing of the ships when it did. They were offered to the ship-

ping industry at a time when freights were still high, and so substantial prices were bid. A very different situation existed when the ex-German ships allotted to this country were offered to British shipowners, again through the medium of Lord Inchcape. Severe depression had, by then, fallen on the shipping industry, and the absorption of the ships, many of which were not of attractive type to British owners, was a very slow matter.

Replying to a question in the House of Commons on May 24 1921, Sir Robert Horne, the Chancellor of the Exchequer, stated that 202 ex-enemy ships allotted to the British Empire for final ownership had been sold, and that 85 merchant ships and 22 trawlers remained unsold. The gross amount realized was £14,523,074. From this gross total there fell to be deducted expenses of repair, delivery, etc., and a considerable part of the purchase money was payable in instalments over a period of years. The net cash then passing was £6,500,000.

War Services of the Mercantile Marine.—All the classes of British ships which form a great mercantile marine rendered services of immense value to the Allies during the war. Merchant vessels, in comparison with warships, were once described as being mere cockleshells, yet their crews faced the hidden dangers of mine and torpedo without flinching. The persistent reduction of the British mercantile marine which proceeded was a matter of extreme gravity to the Allies. Experience showed that the losses of the large and fast liners were, in every way, more formidable than those of the ordinary cargo vessels. When at last the United Kingdom, enthusiastically supported by the United States, bent energies on the construction of merchant vessels, it was the simple cargo steamers that were built. In both countries the plan of building simple vessels of standard type was adopted. Everything that was complicated was ruled out. Straight lines were substituted for curves, and parts were produced in great numbers, so that identical ships could be built rapidly. In the United States the principle of standard construction was carried further than in England. There, steel works, which had never undertaken shipbuilding work before, produced shapes and angles for ships, and the assembling of the parts was carried out by bridge builders and other steel workers who had had no previous experience of shipbuilding. In England fabrication on somewhat similar lines was planned in connexion with the new shipyards on the river Wye, of which control was assumed by the Government, but these plans did not begin to show their full effect until the conclusion of the war made such methods no longer necessary. While, in a case of emergency, a good case could be established for building cargo vessels in mass production, like Ford motor-cars, there was no similar way of building the large liners. In the height of the crisis and, indeed, throughout the war, the building of such vessels yielded place to the need for carriers of food and munitions. Yet the duties devolving on the liners steadily increased. At first a comparatively small number were requisitioned to serve as merchant cruisers, patrol vessels, hospital ships, and transports. The Dardanelles campaign made heavy demands on this type of vessel, and, later, the Salonika expedition. The climax was reached when, in the spring, summer and autumn of 1918 every possible ship that could be provided was needed to transport American troops. Liners were withdrawn from every British service and vessels never intended for such work were put into the N. Atlantic route. It was indeed fortunate for the nation that a large mercantile marine was in existence at the outbreak of war, and the magnificent services of some of the greatest ships will be always remembered.

Of all the crimes committed by Germany at sea, the destruction of the "Lusitania" on May 7 1915 remains the outstanding example. The liner was torpedoed near the Old Head of Kinsale, when 1,195 persons were drowned, including 291 women and 9 children. Represented in tonnage alone this loss was exceeded by the "Britannic," sunk in the Aegean Sea on Nov. 21 1916, by submarine or mine, while employed as a hospital ship. The "Britannic," uncompleted on the outbreak of war, was of 48,158 tons and was the largest White Star liner. The "Lusitania," built in 1907, was of 31,550 tons.

Splendid service was performed by the sister ship "Maure-

tania." At first she was employed in the ordinary trans-Atlantic service, where her speed was of great importance in view of possible attacks by German cruisers. In June 1915 she flew the White Ensign, conveying troops to Mudros for the Gallipoli campaign. Four months later she became a hospital ship. In Dec. 1916 she again became a troopship and brought Canadian troops to this country. Early in 1918 she became an armed cruiser, but was soon engaged in bringing American troops to Europe. She also carried many distinguished passengers whose urgent duties made it necessary for them to cross the Atlantic. Fine service was also rendered by the Cunard liner "Aquitania," of 45,600 tons. Only three round voyages between Liverpool and New York had been made by this great ship before the war. At once she was requisitioned by the Admiralty and was commissioned as a merchant cruiser, leaving Liverpool in this capacity four days after the outbreak of war. She became a transport later and carried 30,000 troops to the Dardanelles; then she became a hospital ship and as such carried 25,000 men. Early in 1918 she was refitted as a transport, and in nine voyages carried 60,000 American troops. The liner was extremely useful in repatriating troops after the Armistice, and in the spring of 1921, in the middle of the shipping depression, had the reputation of being the only ship afloat that was earning any money. Besides carrying large numbers of saloon passengers, she was eminently fitted for the transport of emigrants, of whom she carried enormous numbers from the Continent.

The "Carmania," well known as a Cunard liner before the war, distinguished herself by sinking the German merchant cruiser "Cap Trafalgar" in a duel. The "Laconia," another Cunard liner, shared in the operations in the Rufiji river, East Africa, when the German cruiser "Königsberg" was sunk. Besides the "Lusitania," the Cunard Co. lost the following vessels:—the "Caria," "Veria" (1915), "Franconia," "Alaunia" (1916), "Ivernia," "Lycia," "Folia," "Trachia," "Feltia," "Ultoria," "Volodia," "Vinovia" (1917), "Andania," "Valeria," "Aurania," "Ansonia," "Vandalia," "Carpathia," "Flavia" and "Ascania" (1918). These represented extremely serious losses, and after the Armistice the company put in hand an extensive programme of construction. Unfortunately the cost of building was then on a very high level.

Losses of the White Star Line were also serious and included, besides the "Britannic," the "Oceanic," "Arabic," "Laurentic," "Cymric," "Afric," "Georgic," "Cedric" and "Delphic." Shortly after the outbreak of war, the "Oceanic," "Teutonic," "Cedric," "Celtic" and "Laurentic" were commissioned as armed cruisers. The "Laurentic" was sunk by submarine off the coast of Ireland in Jan. 1917, while carrying gold, of which a substantial proportion was recovered in salvage operations after the Armistice. The "Teutonic," built in 1889, and one of the most famous of the White Star liners, was subsequently acquired by the Government and was later publicly offered for sale. Services of immense value were rendered by the "Olympic" of 46,430 tons. She was employed in carrying troops to Gallipoli and in bringing, first, Canadian troops, then Chinese labour battalions, and, finally, American troops to Europe. Her war record included that of transporting more than 200,000 persons during the period, including the wives and families of Canadian soldiers returning to Canada after the war. Among her special services were the rescue of the company of the super-dreadnought battleship "Audacious," sunk by a mine off the N. coast of Ireland, and the ramming of a large German submarine in the English Channel in May 1918.

Several of the ships of the allied company, the Atlantic Transport Co., were employed in the transport of troops. These included the liners "Minneapolis," "Minnesota," "Minnewaska," "Minnetonka," "Marquette," "Manitou," "Menominee," "Missouri" and "Maryland." Besides carrying troops, the vessels of the Atlantic Transport Co. carried large numbers of horses and mules, for which service the vessels were especially suitable. The losses of the line, representing 24,100 tons, or 43% of the fleet, included all the regular passenger liners which were most favourably known in the trade between London and New York.

Liners of the Canadian Pacific Ocean Services were employed as merchant cruisers and transports. At once the "Alsatian," "Victorian" and "Virginian" were requisitioned and placed in the 10th Cruiser Squadron which was responsible for a share of the blockade of Germany. The "Calgarian" was sunk on March 1 1918 when proceeding in charge of a convoy of 30 ships.

The total number of vessels lost by the P. & O. Co. and its allied lines was 81, representing 491,600 tons, while 14 vessels of 76,600 tons were lost through marine causes. One of the most heroic actions of war at sea was fought between the "Otaki" of the associated New Zealand Shipping Co. (whose commander, Lt. Archibald Bisset Smith, received a posthumous award of the V.C.) and the disguised heavily armed German cruiser "Mocwc." After the "Otaki" had suffered several casualties and much damage had been done to the hull which was heavily on fire, Lt. Smith ordered the boats to be launched in order that the crew might be rescued. He remained on the ship and went down with her when the vessel sank with colours flying.

The Orient Co.'s liners "Otranto," "Orama" and "Otway" were early commissioned as armed cruisers and, at the beginning of 1915, the "Orvieto" and "Ophir" were likewise commissioned. Subsequently the "Ophir" was bought by the Government. Other vessels of the line were employed as transports. The "Otranto" was lost by collision on Oct. 6 1918.

Heavy losses were suffered by the various companies controlled by Sir John Ellerman. In all, 103 ocean vessels, with a total cargo capacity of 600,000 to 750,000 tons, were destroyed. These included the liner "City of Athens" mined off Cape Town in Aug. 1917. The "City of Winchester" was the first merchant vessel to be destroyed during the war, being captured by the German cruiser "Königsberg," while homeward bound from India with a very valuable cargo of produce. Another liner belonging to the Ellerman fleets was mined far from Europe. The "City of Exeter," a fine passenger ship, struck a mine in the Indian Ocean, about 400 m. from Bombay. Number 1 hold filled at once, and the master gave orders for the passengers and crew to leave the ship. Then the master and chief engineer returned and, at grave risk, made a thorough examination of the ship. They decided that, with the exercise of the greatest care, the crippled vessel could reach Bombay under her own steam. The passengers reembarked and the vessel safely arrived in port. This was only one example of fine seamanship, of which there were many hundreds of magnificent cases during the war. When the enemy's submarine campaign became intensified not a voyage through infested waters could have been completed without the exercise of courage of the highest order, and repeatedly the seamanship and endurance of the officers and crews were put to the severest test. There were lurking dangers for the ancient little collier which had to feel her way up and down the North Sea, her one protection being a little gun—slight armament against a powerfully armed submarine; for the great liners which proceeded without escort and relied on their speed, their own guns, their "dazzle painting," and their zig-zag courses to baffle the efforts of the enemy to sink them with, perhaps, several thousand troops on board; and for the slower cargo vessels which, in convoy formation, when thick weather obscured the other ships, ran the very serious risk of collision.

Vessels of the Royal Mail Steam Packet Co. had the distinction of being the first among British liners to be fitted before the war for carrying a gun for defensive purposes. This was in accordance with the policy initiated, before the war, by Mr. Winston Churchill when First Lord of the Admiralty. Royal Mail vessels were largely employed as armed cruisers, transports and hospital ships. As armed cruisers there were commissioned the "Andes," "Arlanza," "Almanzora," "Avon," ("Avoca"), "Ebro" and "Alcantara." The last named, only lightly armed, fought the disguised German raider "Greif" for 20 minutes in the North Sea, and sank with colours flying just before her enemy went to the bottom. The "Asturias" was torpedoed while bearing all the marks of a hospital ship. Other ships of the line which bore the Red Cross were the "Araguaya," "Drina," "Essequibo," "Tagus," "Agadir," "Berbice" and "Balantia"

(renamed "St. Margaret of Scotland"). Many vessels of the fleets were sunk, including the large liners "Amazon," "Drina," and "Merionethshire."

No fewer than six of the Union-Castle liners were torpedoed or mined while serving as hospital ships, namely, the "Galeka," "Braemar Castle," "Dover Castle," "Glenart Castle" (twice), "Gloucester Castle," and "Llandovery Castle." While based on Southampton the hospital ships of the company carried 331,000 British wounded officers and men to port and also landed 8,200 enemy wounded. The liners "Armada Castle," "Edinburgh Castle," "Kinfauns Castle," and "Kildonan Castle" were commissioned as armed merchant cruisers. The company's vessels also carried very large numbers of troops. It was not surprising that, after the Armistice, many months elapsed before a sufficient number of vessels could be again placed in the ordinary S. African passenger service to provide weekly sailings.

Recognition of the services of British shipping during the war was made by the King and his ministers in various speeches. Speaking at the Guildhall on July 29 1919, the King declared that the splendid services of the officers and men of the British mercantile marine had been vital to the successful issue of the war. From day to day these men had been facing death no less than the soldiers in the fighting line, and, even when the submarine menace was at its height, no single British crew ever refused to sail. He urged the re-creation of the merchant navy and the development of the ports as essential if the United Kingdom was to regain its old supremacy.

Men of the mercantile marine marched in the procession of the Allied and Associated Forces through the streets of London on July 19, 1919. There was also a special pageant of the Sea Services on Aug. Bank Holiday 1919. This took the form of a procession of lifeboats, bearing the House flags of all the shipping companies, from the Pool of London to Chelsea. The procession was headed by a launch flying the flag of the Port of London Authority, followed by a steam vessel of Trinity House, with the Duke of Connaught, as Master, on board. Then came a picket boat with a naval officer in charge as escort to the Royal barge. In this were the King and Queen, Queen Alexandra, the Prince of Wales, Prince Albert (afterwards Duke of York) and other members of the Royal Family. Following this was a specially prepared barge bearing the Lords of the Admiralty and then the Lord Mayor, as admiral of the Port of London, in the barge of the commander-in-chief at the Nore. These were followed by launches of the Ministry of Shipping, the Customs and Excise, Lloyd's and the Thames Conservancy. A dozen twelve-oared naval cutters, four picket boats and an armed motor-launch of the navy, models of naval guns, motor and steam lifeboats, a motor-launch carrying Trinity House pilots, steam-boats of the Mercantile Marine Association and boats from the training ships, fishermen's motor drifters, and vessels representing the Missions to Seamen. The rear was brought up by 70 lifeboats towed by tugs bearing the flags of the various shipping ownerships. Bands were placed along the line of route and famous old sea songs were sung. Such a commemoration was unprecedented, but then the services of the mercantile marine during the war were likewise unique.

The Commonwealth Government Line.—In the summer of 1916 a development occurred of great importance to shipping. For some time Australia had been seriously disturbed about the difficulties encountered in arranging for her exportable surplus of wheat, a matter of vital importance to the Commonwealth. With the ever-diminishing supply of tonnage, British vessels had naturally been directed more and more into the N. Atlantic, since it was obviously much quicker to bring wheat to the United Kingdom—less than 3,000 m. across the ocean—than more than 12,000 miles. Mr. W. M. Hughes, the Prime Minister of Australia, arrived in the United Kingdom in March 1916, but he got little satisfaction from the Imperial authorities on the shipping question. He sailed for home in June and, when he was on the water, the announcement was made that he had bought, on account of the Commonwealth Government, 15 second-hand

cargo vessels. The steamers had an average dead-weight carrying capacity of between 7,000 and 8,000 tons, and 10 of them were taken from Messrs. Burrell's Strath line. For the larger vessels the price worked out at about £19 a ton. This was, perhaps, from four to five times greater than the pre-war price, but as events occurred, the purchase proved a profitable one, financially, for Australia. One effect was that the vessels were removed from the United Kingdom Register and were no longer subject to excess profit taxation. This action of Mr. Hughes hardly commended itself to any of the shipping authorities in the United Kingdom, but he had shown unmistakably that full recognition had to be given to the Australian viewpoint. In the autumn of that year the President of the Board of Trade announced that a large purchase had been made of Australian wheat on behalf of the Imperial Government, and that a number of steamers had been requisitioned to proceed to load the wheat in Australia. As the supply of available shipping became steadily less, it proved impracticable to transport all the wheat bought, and immense quantities were stored in Australia until after the conclusion of the war.

The purchase of the 15 cargo vessels represented the foundation of a Commonwealth Government line. Being free from taxation and with freights ruling high, large profits were earned, which made the venture temporarily, at any rate, profitable to the Australian people. A number of German steamers seized in Australia were added to the fleet and, later, ships were built both in Australia and the United Kingdom. In 1919 Mr. W. M. Hughes, on a visit to the United Kingdom, placed contracts for five large steamers with leading builders. These were designed for carrying a large amount of refrigerated cargo, and some hundreds of third-class passengers. Limited accommodation was to be provided for a few passengers in the saloon. The first of these steamers, the "Moreton Bay," of 14,500 tons gross, was launched from Messrs. Vickers's shipyard at Barrow on April 23 1921. It was then asserted that the four other vessels would be in the water during the ensuing few months, and that all the vessels would be in service before the end of 1921. Between the time of the placing of the contracts in 1919 and the time of launching, the cost of ship construction had risen very seriously. All work was done on the "time and lime" principle, by which the owners paid for the cost of materials, the cost of labour, an allowance for overhead charges, and a sum, either as a fixed amount or as a percentage on the outlay, as profit to the builders. The ships were thus understood to have cost considerably more than had been expected, and with freights falling, the problem of making the vessels pay their way was enhanced. A wooden ship programme carried out for Australia in the United States was hardly successful financially. The building of wooden vessels, of which large numbers were constructed for the American mercantile marine, could only be regarded as an emergency measure. The inauguration of the Commonwealth line aroused much criticism from shipping managers, who cordially disliked the idea of a State enterprise. They maintained, and could do so justifiably, that a State enterprise could be carried on without the same consideration for profit and loss as a public company, if, for instance, a Government chose to carry merchandise at below cost price.

The Canadian Merchant Marine.—Canada instituted a line of Government steamers. It found itself after the Armistice with a great fleet of vessels which had been built in the period of emergency. Instead of offering them to the shipping industry, it decided to operate them on account of the nation. A corporation was formed, entitled the Canadian Government Merchant Marine, Ltd., in close conjunction with the Canadian National railways. The policy of the management was to institute new services and to work in coöperation with the existing lines, rather than to compete with them. New services were established to and from the United Kingdom and many parts of the world. In 1920 an agreement was entered into with Messrs. Alfred Holt & Co. for a joint trans-Pacific service to and from Vancouver, and with the British India Co. for a service between Montreal and Indian ports, via the Suez Canal. In the United

Kingdom the Cunard Co. acted as managers for the line. The usual practice in making these arrangements with the shipping companies was for the Canadian National railways to represent the steamship companies in Canada, and for the agents of the shipping companies abroad to act similarly for the railways. This policy of working in conjunction with the shipping companies disarmed criticism, which was very strong in the case of the Australian scheme.

Amalgamation and Fusion Schemes.—Numerous amalgamations and fusion schemes took place between 1910 and 1921. Sir Owen Philipps, who at the beginning of 1910 was chairman of the Royal Mail Steam Packet Co., was particularly active in the policy of fusion. In that year the capital was acquired of the Pacific Steam Navigation Co., which was mainly interested in the trade with the E. and W. coasts of S. America. In the same year a fusion agreement was entered into with Elder, Dempster & Co., Ltd., which owed its development largely to the genius of the late Sir Alfred Jones. In 1911, the capital was acquired of Lamport & Holt, Ltd., largely concerned in the trade between the United Kingdom and also the United States and S. America, and in the same year an agreement was entered into with the Glen Line, Ltd., which is concerned in Far Eastern trade. Incidentally, the Glen Line is notable among British ownerships for its policy of building motor-ships, which is known to have been very successful. In 1912 the capital of the Union-Castle Co. was acquired by the Royal Mail Co. and the Elder Dempster Co. This, perhaps, was the most important of the fusion agreements which Sir Owen Philipps effected. The Union-Castle Co., a consolidation of the old Union and Castle companies in the S. African trade, had been feeling the loss of a great chief in the death of Sir Donald Currie, to whose extraordinary powers the line owed very much. In 1913 control was secured of the Nelson Lines, Ltd., which was and is engaged in the carriage of meat to the United Kingdom from Argentina, together with participation in the passenger trade. In 1917 an interest was acquired in MacAndrew & Co., Ltd., concerned in trade with the Peninsula; in the Coast Lines, Ltd., a consolidation of coasting companies trading round the United Kingdom; and in the Moss Line, Ltd. In 1919 an interest was secured in the old-established ownership of David MacIver & Co., Ltd., in Messrs. Bullard, King & Co., Ltd., and in Messrs. J. & P. Hutchinson, Ltd. While Sir Owen Philipps thus had enormous interests in British shipping, Lord Inchcape was also to the forefront in effecting fusion schemes.

At the end of 1914, Sir Thomas Sutherland retired from the positions of chairman and managing director of the P. & O. Company. For 42 years he had occupied the office of managing director and for 34 years that of chairman. The expansion of the P. & O. Co. will always be associated with his name. His last important act was to effect an amalgamation with the British India Co., of which Lord Inchcape was managing director. On the retirement of Sir Thomas Sutherland, Lord Inchcape became chairman and managing director of the P. & O. Company.

In June 1916, the P. & O. Co. acquired an interest in the New Zealand Shipping Co., which, in turn, controlled the Federal Line trading with Australia. Exactly a year later, in June 1917, a representative interest was secured in the Union Steamship Co. of New Zealand, which not only provided various coasting services in New Zealand, but also maintained services with Australia, British Columbia, and India. In the autumn of 1917 shares were secured in the Hain & Mercantile Steamship Co., and also in the Nourse Line, each of which possessed a considerable amount of cargo tonnage. The fleets of these three companies, together, included 107 steamers of 370,000 tons gross.

Other notable fusions of the war period included the acquisition of a controlling interest in the Prince Line, Ltd., which had been associated with the name of its founder Mr. James Knott. This acquisition, which was effected in Aug. 1916, involved the addition of 37 steamers, mainly cargo vessels, to those controlled by Messrs. Furness, Withy.

In Oct. 1916, Sir John Ellerman, chief of the Ellerman Lines, acquired all the shares of Messrs. Thomas Wilson, Sons & Co., Ltd., the Wilson fleet including nearly 80 vessels of about 200,000 tons. Its services were based on Hull. At almost the same time an agreement was concluded between the Anchor Line (Henderson Bros., Ltd.) and the Donaldson Line, Ltd., for a fusion, under the title of the Anchor-Donaldson Line, with Sir Alfred Booth, chairman of the Cunard Co., as chief of the new formation. The agreement meant that the Cunard Co. secured control of the Donaldson Line, for it already had a controlling interest in the Anchor Line.

Shipowners' Associations.—Important work was done by the Liverpool Steamship Owners' Association, especially through the war period. It acted on the principles upon which it was founded in 1848. These were, broadly, that the growth and prosperity of the British mercantile marine is dependent on the enterprise, skill and ability of the individuals directly concerned, and that neither State control nor State aid can prove an effective substitute for these qualities. The Association has not sought to interfere with the individual freedom of its members. It has, however, consistently opposed

Liners of the Canadian Pacific Ocean Services were employed as merchant cruisers and transports. At once the "Alsatian," "Victorian" and "Virginian" were requisitioned and placed in the 10th Cruiser Squadron which was responsible for a share of the blockade of Germany. The "Calgarian" was sunk on March 1 1918 when proceeding in charge of a convoy of 30 ships.

The total number of vessels lost by the P. & O. Co. and its allied lines was 81, representing 491,600 tons, while 14 vessels of 76,600 tons were lost through marine causes. One of the most heroic actions of war at sea was fought between the "Otaki" of the associated New Zealand Shipping Co. (whose commander, Lt. Archibald Bisset Smith, received a posthumous award of the V.C.) and the disguised heavily armed German cruiser "Mocwc." After the "Otaki" had suffered several casualties and much damage had been done to the hull which was heavily on fire, Lt. Smith ordered the boats to be launched in order that the crew might be rescued. He remained on the ship and went down with her when the vessel sank with colours flying.

The Orient Co.'s liners "Otranto," "Orama" and "Otway" were early commissioned as armed cruisers and, at the beginning of 1915, the "Orvieto" and "Ophir" were likewise commissioned. Subsequently the "Ophir" was bought by the Government. Other vessels of the line were employed as transports. The "Otranto" was lost by collision on Oct. 6 1918.

Heavy losses were suffered by the various companies controlled by Sir John Ellerman. In all, 103 ocean vessels, with a total cargo capacity of 600,000 to 750,000 tons, were destroyed. These included the liner "City of Athens" mined off Cape Town in Aug. 1917. The "City of Winchester" was the first merchant vessel to be destroyed during the war, being captured by the German cruiser "Königsberg," while homeward bound from India with a very valuable cargo of produce. Another liner belonging to the Ellerman fleets was mined far from Europe. The "City of Exeter," a fine passenger ship, struck a mine in the Indian Ocean, about 400 m. from Bombay. Number 1 hold filled at once, and the master gave orders for the passengers and crew to leave the ship. Then the master and chief engineer returned and, at grave risk, made a thorough examination of the ship. They decided that, with the exercise of the greatest care, the crippled vessel could reach Bombay under her own steam. The passengers reembarked and the vessel safely arrived in port. This was only one example of fine seamanship, of which there were many hundreds of magnificent cases during the war. When the enemy's submarine campaign became intensified not a voyage through infested waters could have been completed without the exercise of courage of the highest order, and repeatedly the seamanship and endurance of the officers and crews were put to the severest test. There were lurking dangers for the ancient little collier which had to feel her way up and down the North Sea, her one protection being a little gun—slight armament against a powerfully armed submarine; for the great liners which proceeded without escort and relied on their speed, their own guns, their "dazzle painting," and their zig-zag courses to baffle the efforts of the enemy to sink them with, perhaps, several thousand troops on board; and for the slower cargo vessels which, in convoy formation, when thick weather obscured the other ships, ran the very serious risk of collision.

Vessels of the Royal Mail Steam Packet Co. had the distinction of being the first among British liners to be fitted before the war for carrying a gun for defensive purposes. This was in accordance with the policy initiated, before the war, by Mr. Winston Churchill when First Lord of the Admiralty. Royal Mail vessels were largely employed as armed cruisers, transports and hospital ships. As armed cruisers there were commissioned the "Andes," "Arlanza," "Almanzora," "Avon," ("Avoca"), "Ebro" and "Alcantara." The last named, only lightly armed, fought the disguised German raider "Greif" for 20 minutes in the North Sea, and sank with colours flying just before her enemy went to the bottom. The "Asturias" was torpedoed while bearing all the marks of a hospital ship. Other ships of the line which bore the Red Cross were the "Araguaya," "Drina," "Essequibo," "Tagus," "Agadir," "Berbice" and "Balantia"

(renamed "St. Margaret of Scotland"). Many vessels of the fleets were sunk, including the large liners "Amazon," "Drina," and "Merionethshire."

No fewer than six of the Union-Castle liners were torpedoed or mined while serving as hospital ships, namely, the "Galeka," "Braemar Castle," "Dover Castle," "Glenart Castle" (twice), "Gloucester Castle," and "Llandovery Castle." While based on Southampton the hospital ships of the company carried 331,000 British wounded officers and men to port and also landed 8,200 enemy wounded. The liners "Armada Castle," "Edinburgh Castle," "Kinfauns Castle," and "Kildonan Castle" were commissioned as armed merchant cruisers. The company's vessels also carried very large numbers of troops. It was not surprising that, after the Armistice, many months elapsed before a sufficient number of vessels could be again placed in the ordinary S. African passenger service to provide weekly sailings.

Recognition of the services of British shipping during the war was made by the King and his ministers in various speeches. Speaking at the Guildhall on July 29 1919, the King declared that the splendid services of the officers and men of the British mercantile marine had been vital to the successful issue of the war. From day to day these men had been facing death no less than the soldiers in the fighting line, and, even when the submarine menace was at its height, no single British crew ever refused to sail. He urged the re-creation of the merchant navy and the development of the ports as essential if the United Kingdom was to regain its old supremacy.

Men of the mercantile marine marched in the procession of the Allied and Associated Forces through the streets of London on July 19, 1919. There was also a special pageant of the Sea Services on Aug. Bank Holiday 1919. This took the form of a procession of lifeboats, bearing the House flags of all the shipping companies, from the Pool of London to Chelsea. The procession was headed by a launch flying the flag of the Port of London Authority, followed by a steam vessel of Trinity House, with the Duke of Connaught, as Master, on board. Then came a picket boat with a naval officer in charge as escort to the Royal barge. In this were the King and Queen, Queen Alexandra, the Prince of Wales, Prince Albert (afterwards Duke of York) and other members of the Royal Family. Following this was a specially prepared barge bearing the Lords of the Admiralty and then the Lord Mayor, as admiral of the Port of London, in the barge of the commander-in-chief at the Nore. These were followed by launches of the Ministry of Shipping, the Customs and Excise, Lloyd's and the Thames Conservancy. A dozen twelve-oared naval cutters, four picket boats and an armed motor-launch of the navy, models of naval guns, motor and steam lifeboats, a motor-launch carrying Trinity House pilots, steam-boats of the Mercantile Marine Association and boats from the training ships, fishermen's motor drifters, and vessels representing the Missions to Seamen. The rear was brought up by 70 lifeboats towed by tugs bearing the flags of the various shipping ownerships. Bands were placed along the line of route and famous old sea songs were sung. Such a commemoration was unprecedented, but then the services of the mercantile marine during the war were likewise unique.

The Commonwealth Government Line.—In the summer of 1916 a development occurred of great importance to shipping. For some time Australia had been seriously disturbed about the difficulties encountered in arranging for her exportable surplus of wheat, a matter of vital importance to the Commonwealth. With the ever-diminishing supply of tonnage, British vessels had naturally been directed more and more into the N. Atlantic, since it was obviously much quicker to bring wheat to the United Kingdom—less than 3,000 m. across the ocean—than more than 12,000 miles. Mr. W. M. Hughes, the Prime Minister of Australia, arrived in the United Kingdom in March 1916, but he got little satisfaction from the Imperial authorities on the shipping question. He sailed for home in June and, when he was on the water, the announcement was made that he had bought, on account of the Commonwealth Government, 15 second-hand

1922, that the world's merchant shipping since 1914 had been actually increased by more than 10,000,000 tons. Unfortunately for the shipping industry, the world's trade had not developed in proportion. Owing to the complete breakdown of credit in some countries trade was practically at a standstill.

An unprecedented step was taken by the Register in April 1921, when issuing its shipbuilding returns for the first quarter of the year. It issued with these returns a statement to the effect that, as the times were not normal, the figures of tonnage reported to be under construction did not provide a true index of the relative position of the shipbuilding industry as compared with, say, 12 months previously.

The total tonnage under construction in the United Kingdom at the end of March 1921 was given as 3,798,500 tons represented by 884 vessels. In ordinary times such an amount of work in hand would have indicated great activity and prosperity in the shipbuilding industry. It compared, for example, with 1,890,800 tons under construction at the end of March 1914, showing an increase of 1,907,700 tons, and with 1,722,100 tons under construction at the end of June 1914, the last quarter completed before the outbreak of the war. But the amount of tonnage stated to be in course of construction at the end of March 1921 included a considerable amount on which work had been suspended, owing to the heavy fall in shipping values consequent on the severe decline in freights and the corresponding decline in the demand for tonnage. The tonnage on which work had been suspended in this way amounted to 497,000 tons. There were also included in the total figures some 350,000 tons, the completion of which had been delayed owing to the cessation of work by ship joiners. To arrive at comparative figures, it was therefore necessary to deduct these two figures, amounting together to 847,000 tons, from the amount of tonnage described as being under construction. The total figures of tonnage on which work was actually proceeding at the end of March 1921 was thereby reduced to 2,951,500 tons, showing an increase of 847,000 tons over March 1914.

There would have been grounds for satisfaction in such an increase if the world's commerce had been active. Unfortunately, enormous numbers of the world's inhabitants were taking no part in international commerce, and, further, there were immense numbers who were not producing goods or working at the same rate as before the war. Consequently the construction of so much tonnage, although the work was proceeding at a slow pace, could not be regarded with unmixed satisfaction. Cancellations of shipbuilding contracts by owners were common, and large sums were paid in order that owners might be relieved of their commitments. The surplus of ordinary cargo steamships was especially large. The losses of mail and passenger liners during the war had not been made good, but the high cost of building tended to prevent replacements.

As compared with the figures for the quarter ended Dec. 1920, there was a reduction in the shipping launched during the first quarter of 1921 of 146,000 tons. The tonnage started during the quarter declined by 113,000 tons, while in the tonnage in preparation, but not actually commenced, there was a fall of 75%, as compared with the figures of the first quarter of 1920. Attention was called by Lloyd's Register both at the end of 1920 and in the beginning of 1921 to the lower rate of construction as compared with pre-war times. In 1913 the average amount of tonnage completed during each quarter was over 23% of the total work in hand at the beginning of the quarter, whereas the figures for 1920 fell below 13%. During the first quarter of 1921 the output fell as low as 8% of that under construction at the beginning of the year.

The total amount of tonnage being built abroad was 3,288,100 tons—not quite so large an amount as the tonnage described as being under construction in the United Kingdom, but actually larger than that on which work was actively proceeding there. The Register pointed out that the returns for foreign countries, unlike those for the United Kingdom, were not subject to any material reduction on account of suspended or delayed work, of which there appeared to be comparatively little in other countries. The shipping being built abroad was less by 183,000 tons than that under construction at the end of 1920. The decline was due to the continued decrease in the United States of America, where the tonnage under construction was less by 27% than that building at the beginning of 1919. Apart from the United States, the countries in which the largest amount of shipbuilding was taking place were France, with 427,100 tons, an increase for the quarter of about 30,000 tons; Holland with 417,600 tons; Italy with 351,600 tons; and Japan with 294,300 tons, an increase of 46,000 tons.

The returns showed that there were then 187 steamers and motorships, each of over 1,000 tons, with a total of 1,320,100 tons, under construction for the carriage of oil in bulk. Of the total number, 84, of 557,000 tons, were under construction in the United Kingdom, and 82, of 632,000 tons, in the United States. In the former the oil-tank tonnage represented 57% of the total amount of construction. The tonnage of vessels under construction to be fitted with internal combustion engines amounted to 503,800 tons.

A highly unsatisfactory feature was the diversion of a large amount of British shipping from British to foreign shipyards for reconditioning. This was due to a refusal on the part of the ship joiners to accept the lower wages proposed by the employers and the consequent cessation of work by the ship joiners in the United Kingdom for many months. Large liners were diverted to Dutch and French ship re-

pairing works. The work of reconditioning was essential, and the stoppage by the ship joiners meant the loss of a large amount of work to the United Kingdom, which, it was to be feared, might have a far-reaching effect on the British industry.

Condition and Prospects.—What might be described as a bird's-eye view of the state of the shipping industry during 1910-21 is afforded by the course of prices of a new, ready, 7,500-ton cargo steamer "as recorded in the chart published by the weekly shipping journal *Fairplay* and described as "Fairplay's Curve." This type of vessel may be considered representative of ordinary cargo steamers. In 1910 the price of such a vessel was £37,000. Prices then rose sharply and by the end of 1911 a price of £47,000 was reached. A further rise took place in 1912 to £58,000. That year, as has been shown, was a prosperous one for shipping, and from the high point reached, values fell to £48,000 at the end of 1913. A further drop occurred in 1914 to £43,000. The great rise then began. By the end of 1914 the price had advanced to £60,000. In 1915 prices more than doubled and £125,000 was reached. In 1916 there was a further advance to £188,000. The effect of the Excess Profits duty was seen in 1917 and values fell to £165,000. In 1918 there was a recovery to £181,000 and then a fall to £169,000. An extraordinary rise took place in 1919, the high price of £232,000 being reached. Early in 1920 there was a further upward movement. Then a great and steady fall began and by the end of the year the value of £105,000 had been reached. In the first six months of 1920, values again receded. On May 24 two new, ready steamers of 9,250 tons dead-weight built by the Furness Shipbuilding Co. to Lloyd's highest class were sold for £85,000 each, representing rather more than £9 a ton. These ships were of the shelter-deck type, with the tonnage openings closed. Vessels of similar size with tonnage openings would carry only 8,300 tons dead-weight, and on that basis the prices bid for the two ships appear somewhat better. Another ship which was of 5,500 tons dead-weight and was built by Charles Hill & Sons, Ltd., of Bristol, was sold for £40,000, representing only rather more than £7 a ton. This particular ship had not been launched, and was not expected to be ready for sea for at least two months.

The Chamber of Shipping estimated that at the beginning of 1921 there were laid up in the United Kingdom, the United States and Scandinavian ports, 5,000,000 tons dead-weight of shipping, or, approximately 3,000,000 gross. This amount of tonnage was made up of 2,250,000 tons in the United Kingdom, represented by 600 vessels, of 2,000,000 tons in the United States represented by 250 vessels, and of 750,000 tons represented by 428 vessels in Scandinavian ports. In addition, many vessels were laid up in Spain, Italy, Japan and other countries, and in the early months of 1921, the amount of tonnage laid up throughout the world steadily increased.

In 1920 there took place the greatest fall in freights that has ever been recorded. The extent of the drop is shown by the movement of the time charter rate, i.e. the monthly rate of hire for ordinary cargo steamers. When vessels are chartered in this way the owners provide and pay the crews and pay for the stores. The charterers pay for the coal, since the amount consumed and the cost depend upon the trade into which the vessel is put. At the beginning of 1920 the usual time charter rate for cargo steamers was 30s. a ton dead-weight. By midsummer the rate had dropped to 20s. a ton or rather less. By the end of the year the rate had fallen to 10s. a ton, and with very little inquiry it fell further. By the end of the first quarter of 1921 steamers were chartered at a rate of 6s. a ton. There were also heavy falls in the voyage rates.

As compared with maximum rates during the war for free British steamers bringing grain from Argentina of about 183s. a ton, the freight early in 1921 had fallen to about 35s. Then, when the coal stoppage occurred at the end of April, rates advanced, owing to the necessity of steamers proceeding from this country in ballast, and to the difficulty of securing bunkers. By the end of May, rates of about 57s. 6d. a ton were being quoted for vessels that were available for immediate loading. It was generally accepted in shipping circles that a freight of about 50s. was necessary to cover the cost of sending a vessel to S. America in ballast and bringing her home with a cargo of grain. The fact that, before the war, cargoes of coal had always been available from the United Kingdom meant competition for the homeward voyage and enabled freights to be restricted. The new conditions were distinctly serious for the shipping industry.

Coal also represented a serious problem for the liner companies. Sir Owen Philipps, chairman of the Royal Mail Steam Packet Co., gave some figures respecting comparative costs at the annual meeting of the company in June 1921. He stated that in 1902 the average cost of all coal consumed by the company's steamers in all ports served, including rail carriage and freight, was exactly 22s. a ton. In 1903, the average price had increased to 22s. 3d., while 10 years later, in 1913, the average cost, including railage and freight, had increased to 22s. 11d., which was then considered a very high average price. In 1920, the average cost per ton of all coal consumed by the company's steamers, including railage and freight, was 120s. 1d. Early in 1921 the price fell very considerably, largely owing to the supply of coal by Germany to France and Belgium, with a consequent falling off in the demand for British coal. Then when the stoppage at the British collieries had been proceeding for some little time, and stocks were being exhausted, British shipping had to look to the Continent for supplies.

The Cunard and White Star companies were in a favourable position as regards the great trans-Atlantic liners, "Aquitania," of 45,600 tons, and "Olympic," of 46,300 tons, since these vessels had been adapted to the use of oil fuel in 1920. Oil fuel, after the war, increased in popularity, although some owners hesitated to commit themselves too much to it, owing to fears that supplies would not be sufficiently abundant, and planned their vessels with a view to the use of either oil or coal. Scandinavian owners, especially, pinned their faith to motor-engines, and it was notable that while coal-burning steamers were laid up idle, motor vessels belonging to the same ownership were being profitably employed. There was good reason to believe that an extensive development of the use of motor-engines was to be expected. It was quite certain in 1921 that a strenuous competitive period lay ahead for shipping, and owners had to take into account all possible measures conducive to cheap transport at sea.

(C. MA.)

(2) UNITED STATES

From the founding of the Federal Government in 1789 onward the United States has possessed a considerable merchant marine. For a hundred years it was the second power in amount of merchant tonnage in the world, surpassed only by the United Kingdom. From the end of the Civil War in 1865 to the outbreak of the World War in 1914, though the American flag was infrequently seen in foreign waters, a great and valuable merchant shipping was in existence, with well-equipped shipyards and a large force of officers and seamen, chiefly employed in home trade on the Great Lakes or on the Atlantic, Gulf and Pacific seaboard with their insular dependencies. The American people at no time in their history have been out of intimate touch with shipbuilding and navigation.

Unlike other nations the United States has steadily maintained an important and increasing waterborne domestic commerce capable of holding its own with formidable railway competition. This coastwise commerce, including the trade with Alaska, Porto Rico and Hawaii, by an unshaken national policy, has been reserved entirely to American vessels, and has had a significant bearing on the development of the American merchant marine. It is interesting to recall that in 1860, the year before the opening of the Civil War, the commercial fleet of the United States was divided almost equally between 2,379,396 gross tons registered for foreign commerce and 2,644,867 tons enrolled or licensed for coastwise carrying. In 1866, the year after the close of the Civil War, the registered foreign trade fleet, as a result of the war, had fallen off to 1,387,756 gross tons—a decrease of almost a million tons—while the coastwise fleet had increased to 3,381,522 tons. This tendency of the foreign trade shipping to decrease, and of the domestic trade fleet to grow, was even more manifest by the year 1910, when the former had fallen to 782,517 gross tons, or actually less than the 981,019 tons which the United States had possessed a century earlier in 1810, while the coastal fleet had increased to 6,668,966 tons, or more than twice as much as the entire American commercial shipping of 1860.

This sharp contrast between the steady decline of the overseas tonnage and the unbroken advance of the domestic tonnage is attributable to the intensity of foreign competition in the one trade and to the absence of it in the other. Through those years the wages of American crews and their subsistence and general style of living imposed a higher cost upon the operation of American ships, and American-built ships in addition bore a substantially higher cost of construction. Moreover, American laws and regulations governing ships have contributed somewhat to this higher expense by their more exacting character. Against this higher expense the coastwise vessels from 1860 onward were absolutely protected by the exclusion of foreign vessels from domestic trade, while the overseas vessels were protected in no way whatever, except for casual postal subsidies to a few regular lines. In view of the fact that from 1860 high protection has been almost continuous in the United States, this exception of the most intensely competitive of industries, ocean shipping, is difficult to understand. The generally accepted explanation is that it has not been possible at any time to present a definite form of national encouragement to the overseas shipping industry which was acceptable to all of the various sections of the country. Subsidies have almost been voted by Congress several times. Discriminating customs duties and tonnage dues, an expedient first adopted in 1789 and maintained in whole or in part for 60 years thereafter, have had a powerful advocacy but, as a matter of fact, have never been made effective because of general commercial treaties which have forbidden them. "Free ships"—that is, the free admission and registry of foreign-built vessels instead of the general prohibition of American registry for foreign-built vessels obtaining since 1789—were adopted

for vessels of less than five years of age in the Panama Canal Act of 1912, but had remained wholly futile up to the war of 1914, which suddenly gave exceptional value to the flag of the greatest neutral.

Pre-war Position.—American overseas shipping as distinguished from coastwise shipping reached almost the lowest ebb in 1910, when only 782,517 gross tons were recorded by the Commissioner of Navigation as registered for foreign commerce and sufficed to convey only 8.7% of the total imports and exports of the United States. Though relatively little effort had been bestowed upon the promotion of foreign commerce in these years of wonderful domestic development, the total foreign trade of the United States had increased markedly from a value of \$762,288,550 in 1860 to \$2,982,799,622 in 1910. Whatever the cause of the decline of the overseas American merchant marine, it had certainly not been from any lack of cargoes.

No change or event of consequence marked the years from 1910 to 1914 in the annals of American shipbuilding or navigation. Official records show the amount of shipbuilding, the total registered overseas and the total coastwise tonnage, the total merchant marine and the proportion of American overseas commerce conveyed in American ships, for the five fiscal years ending June 30 1914, to have been as follows:—

Year	Ships Built	Registered for Foreign Trade	Enrolled or Licensed for Coastwise Trade	Total Merchant Marine	Proportion of Value of Imports & Exports Carried in American Ships
	Gross tons	Gross tons	Gross tons	Gross tons	Per cent
1910	342,068	782,517	6,668,966	7,508,082	8.7
1911	291,162	863,495	6,720,313	7,638,790	8.7
1912	232,669	923,225	6,737,046	7,714,183	9.4
1913	346,155	1,019,165	6,816,980	7,886,518	8.9
1914	316,250	1,066,288	5,818,363	7,928,688	8.6

These records indicate a condition of virtual stagnation in the American merchant marine during the period immediately before the World War. New construction was only slightly in excess year after year of tonnage lost or worn out and abandoned. It was a time of disheartenment among those who desired to see an adequate ocean service under the American flag, and a valuable naval reserve for an emergency.

In the Panama Canal Act of Aug. 24 1912 Section 5 provided that "No tolls shall be levied upon vessels engaged in the coastwise trade of the United States." It was contended before and after the passage of this Act that it contravened the provision of the Hay-Pauncefote treaty, that "The canal shall be free and open . . . to the vessels of commerce and war of all nations . . . on terms of entire equality, so that there shall be no discrimination against any nation or its citizens or subjects in respect to the conditions or charges of traffic or otherwise." President Wilson, who had originally favoured this exemption of American coastwise ships, and had been elected on a platform approving it, unexpectedly early in 1914 advocated the repeal of the exemption provision on the ground that it was in conflict with the treaty, and also that "repeal be granted by Congress in support of the foreign policy of the Administration." After an animated debate in the course of which the President was opposed by several senators of his own party, and at the same time upheld by some eminent Republicans, including Senator Root of New York, repeal was finally accomplished. No actual advantage had accrued to American coastwise vessels from the toll exemption, for the canal had not then been opened to commerce. It was opened Aug. 15 1914, and was utilized in its first year by 1,317 vessels, including merchant carriers, men-of-war and yachts, of an aggregate net Panama Canal tonnage of 4,596,644. Tolls paid amounted to \$5,216,149. In the coast-to-coast fleet of the United States there was soon a notable expansion, and new and important steamers of 10,000 or 12,000 tons dead-weight capacity were plying on the route shortened from 13,000 m. via the Straits of Magellan to 6,000 m. via the Canal. These large coastwise steamers were destined to prove of abundant value to American overseas commerce in the emergency presented by the war.

War Period.—When the World War began in Europe Aug. 1 1914 all but 8.6% of the imports and exports of the United States were being conveyed in foreign vessels, chiefly of British and German nationality. The first result was the voluntary "interning" in American harbours of a considerable fleet of

1922, that the world's merchant shipping since 1914 had been actually increased by more than 10,000,000 tons. Unfortunately for the shipping industry, the world's trade had not developed in proportion. Owing to the complete breakdown of credit in some countries trade was practically at a standstill.

An unprecedented step was taken by the Register in April 1921, when issuing its shipbuilding returns for the first quarter of the year. It issued with these returns a statement to the effect that, as the times were not normal, the figures of tonnage reported to be under construction did not provide a true index of the relative position of the shipbuilding industry as compared with, say, 12 months previously.

The total tonnage under construction in the United Kingdom at the end of March 1921 was given as 3,798,500 tons represented by 884 vessels. In ordinary times such an amount of work in hand would have indicated great activity and prosperity in the shipbuilding industry. It compared, for example, with 1,890,800 tons under construction at the end of March 1914, showing an increase of 1,907,700 tons, and with 1,722,100 tons under construction at the end of June 1914, the last quarter completed before the outbreak of the war. But the amount of tonnage stated to be in course of construction at the end of March 1921 included a considerable amount on which work had been suspended, owing to the heavy fall in shipping values consequent on the severe decline in freights and the corresponding decline in the demand for tonnage. The tonnage on which work had been suspended in this way amounted to 497,000 tons. There were also included in the total figures some 350,000 tons, the completion of which had been delayed owing to the cessation of work by ship joiners. To arrive at comparative figures, it was therefore necessary to deduct these two figures, amounting together to 847,000 tons, from the amount of tonnage described as being under construction. The total figures of tonnage on which work was actually proceeding at the end of March 1921 was thereby reduced to 2,951,500 tons, showing an increase of 847,000 tons over March 1914.

There would have been grounds for satisfaction in such an increase if the world's commerce had been active. Unfortunately, enormous numbers of the world's inhabitants were taking no part in international commerce, and, further, there were immense numbers who were not producing goods or working at the same rate as before the war. Consequently the construction of so much tonnage, although the work was proceeding at a slow pace, could not be regarded with unmixed satisfaction. Cancellations of shipbuilding contracts by owners were common, and large sums were paid in order that owners might be relieved of their commitments. The surplus of ordinary cargo steamships was especially large. The losses of mail and passenger liners during the war had not been made good, but the high cost of building tended to prevent replacements.

As compared with the figures for the quarter ended Dec. 1920, there was a reduction in the shipping launched during the first quarter of 1921 of 146,000 tons. The tonnage started during the quarter declined by 113,000 tons, while in the tonnage in preparation, but not actually commenced, there was a fall of 75%, as compared with the figures of the first quarter of 1920. Attention was called by Lloyd's Register both at the end of 1920 and in the beginning of 1921 to the lower rate of construction as compared with pre-war times. In 1913 the average amount of tonnage completed during each quarter was over 23% of the total work in hand at the beginning of the quarter, whereas the figures for 1920 fell below 13%. During the first quarter of 1921 the output fell as low as 8% of that under construction at the beginning of the year.

The total amount of tonnage being built abroad was 3,288,100 tons—not quite so large an amount as the tonnage described as being under construction in the United Kingdom, but actually larger than that on which work was actively proceeding there. The Register pointed out that the returns for foreign countries, unlike those for the United Kingdom, were not subject to any material reduction on account of suspended or delayed work, of which there appeared to be comparatively little in other countries. The shipping being built abroad was less by 183,000 tons than that under construction at the end of 1920. The decline was due to the continued decrease in the United States of America, where the tonnage under construction was less by 27% than that building at the beginning of 1919. Apart from the United States, the countries in which the largest amount of shipbuilding was taking place were France, with 427,100 tons, an increase for the quarter of about 30,000 tons; Holland with 417,600 tons; Italy with 351,600 tons; and Japan with 294,300 tons, an increase of 46,000 tons.

The returns showed that there were then 187 steamers and motorships, each of over 1,000 tons, with a total of 1,320,100 tons, under construction for the carriage of oil in bulk. Of the total number, 84, of 557,000 tons, were under construction in the United Kingdom, and 82, of 632,000 tons, in the United States. In the former the oil-tank tonnage represented 57% of the total amount of construction. The tonnage of vessels under construction to be fitted with internal combustion engines amounted to 503,800 tons.

A highly unsatisfactory feature was the diversion of a large amount of British shipping from British to foreign shipyards for reconditioning. This was due to a refusal on the part of the ship joiners to accept the lower wages proposed by the employers and the consequent cessation of work by the ship joiners in the United Kingdom for many months. Large liners were diverted to Dutch and French ship re-

pairing works. The work of reconditioning was essential, and the stoppage by the ship joiners meant the loss of a large amount of work to the United Kingdom, which, it was to be feared, might have a far-reaching effect on the British industry.

Condition and Prospects.—What might be described as a bird's-eye view of the state of the shipping industry during 1910-21 is afforded by the course of prices of a new, ready, 7,500-ton cargo steamer "as recorded in the chart published by the weekly shipping journal *Fairplay* and described as "Fairplay's Curve." This type of vessel may be considered representative of ordinary cargo steamers. In 1910 the price of such a vessel was £37,000. Prices then rose sharply and by the end of 1911 a price of £47,000 was reached. A further rise took place in 1912 to £58,000. That year, as has been shown, was a prosperous one for shipping, and from the high point reached, values fell to £48,000 at the end of 1913. A further drop occurred in 1914 to £43,000. The great rise then began. By the end of 1914 the price had advanced to £60,000. In 1915 prices more than doubled and £125,000 was reached. In 1916 there was a further advance to £188,000. The effect of the Excess Profits duty was seen in 1917 and values fell to £165,000. In 1918 there was a recovery to £181,000 and then a fall to £169,000. An extraordinary rise took place in 1919, the high price of £232,000 being reached. Early in 1920 there was a further upward movement. Then a great and steady fall began and by the end of the year the value of £105,000 had been reached. In the first six months of 1920, values again receded. On May 24 two new, ready steamers of 9,250 tons dead-weight built by the Furness Shipbuilding Co. to Lloyd's highest class were sold for £85,000 each, representing rather more than £9 a ton. These ships were of the shelter-deck type, with the tonnage openings closed. Vessels of similar size with tonnage openings would carry only 8,300 tons dead-weight, and on that basis the prices bid for the two ships appear somewhat better. Another ship which was of 5,500 tons dead-weight and was built by Charles Hill & Sons, Ltd., of Bristol, was sold for £40,000, representing only rather more than £7 a ton. This particular ship had not been launched, and was not expected to be ready for sea for at least two months.

The Chamber of Shipping estimated that at the beginning of 1921 there were laid up in the United Kingdom, the United States and Scandinavian ports, 5,000,000 tons dead-weight of shipping, or, approximately 3,000,000 gross. This amount of tonnage was made up of 2,250,000 tons in the United Kingdom, represented by 600 vessels, of 2,000,000 tons in the United States represented by 250 vessels, and of 750,000 tons represented by 428 vessels in Scandinavian ports. In addition, many vessels were laid up in Spain, Italy, Japan and other countries, and in the early months of 1921, the amount of tonnage laid up throughout the world steadily increased.

In 1920 there took place the greatest fall in freights that has ever been recorded. The extent of the drop is shown by the movement of the time charter rate, i.e. the monthly rate of hire for ordinary cargo steamers. When vessels are chartered in this way the owners provide and pay the crews and pay for the stores. The charterers pay for the coal, since the amount consumed and the cost depend upon the trade into which the vessel is put. At the beginning of 1920 the usual time charter rate for cargo steamers was 30s. a ton dead-weight. By midsummer the rate had dropped to 20s. a ton or rather less. By the end of the year the rate had fallen to 10s. a ton, and with very little inquiry it fell further. By the end of the first quarter of 1921 steamers were chartered at a rate of 6s. a ton. There were also heavy falls in the voyage rates.

As compared with maximum rates during the war for free British steamers bringing grain from Argentina of about 183s. a ton, the freight early in 1921 had fallen to about 35s. Then, when the coal stoppage occurred at the end of April, rates advanced, owing to the necessity of steamers proceeding from this country in ballast, and to the difficulty of securing bunkers. By the end of May, rates of about 57s. 6d. a ton were being quoted for vessels that were available for immediate loading. It was generally accepted in shipping circles that a freight of about 50s. was necessary to cover the cost of sending a vessel to S. America in ballast and bringing her home with a cargo of grain. The fact that, before the war, cargoes of coal had always been available from the United Kingdom meant competition for the homeward voyage and enabled freights to be restricted. The new conditions were distinctly serious for the shipping industry.

Coal also represented a serious problem for the liner companies. Sir Owen Philipps, chairman of the Royal Mail Steam Packet Co., gave some figures respecting comparative costs at the annual meeting of the company in June 1921. He stated that in 1902 the average cost of all coal consumed by the company's steamers in all ports served, including rail carriage and freight, was exactly 22s. a ton. In 1903, the average price had increased to 22s. 3d., while 10 years later, in 1913, the average cost, including railage and freight, had increased to 22s. 11d., which was then considered a very high average price. In 1920, the average cost per ton of all coal consumed by the company's steamers, including railage and freight, was 120s. 1d. Early in 1921 the price fell very considerably, largely owing to the supply of coal by Germany to France and Belgium, with a consequent falling off in the demand for British coal. Then when the stoppage at the British collieries had been proceeding for some little time, and stocks were being exhausted, British shipping had to look to the Continent for supplies.

As a result, unheard-of achievements in the way of production speed were soon recorded. The "Tuckahoe," a 5,500 dead-weight ton collier, was completed by the N.Y. Shipbuilding Co. at Camden, N. J., in 37 calendar days; the "Crawl Keys," a 5,500-ton freighter, at the Great Lakes Engineering Works, Ecorse, Mich., in 34 days. Heavy 8,800-ton freighters were built in Pacific shipyards in from 78 to 88 days, where before the war from six to ten months would have been required. The Bethlehem Shipbuilding Corp. yard at Alameda, Cal., launched the 12,000-ton cargo liner "Invincible" 31 days after the laying of her keel. It was thoroughly realized that such haste would often mar the quality of the work—that ships built in such brief time might well prove less efficient and enduring. But the Government and the builders realized also that it was a race with the German submarines, and that enough ships must be provided by whatever methods at whatever cost to feed and supply the Allies, and to carry and sustain the troops that would soon be crowding over.

One expedient which greatly helped toward quick production was the fabricated ship. One factor in the choice of this plan of construction, never adopted on a large scale before, was the success of the Submarine Boat Corp. in building in 1916 a fleet of 550 submarine-chasers for the British Government. These little vessels were of wood. It was obvious that steel would lend itself more readily to fabrication, and Mr. Henry R. Sutphen, Vice-President of the Submarine Boat Corp., submitted to the Emergency Fleet Corp. a proposal for manufacturing standard steel ships from the same kind of commercial structural steel that is employed for buildings and bridges. This plan was successfully carried out. Structural plates, shapes and other material were prepared at plants all over the country where they could be produced to the best advantage, and shipped to the assembling yards for final riveting together, a certain number of rivets indeed having already been driven before the material arrived. One hundred and fifty fabricated steamers of about 5,000 tons dead-weight were contracted for with the Submarine Boat Corp.'s yard on Newark Bay, N. J. One hundred and eighty fabricated ships of about 7,500 tons were ordered from the great Hog I. Shipyard near Philadelphia. This shipyard, the largest in the world, with 50 ways, was created in less than six months under the direction of the engineers of the American International Corp., out of what had been a waste marsh on the shores of the Delaware River. With its ways, storehouses and workshops it covered 900 acres. Its cost was \$66,000,000. On the completion of its building programme, and when its ships were no longer needed, it afforded an admirable site for a great rail and ship terminal.

Several hundred wooden steamers of a dead-weight capacity of from 3,500 to 5,000 tons were ordered by the Emergency Fleet Corp. in the war emergency. There was much criticism of this project, for the building of wooden steamers for overseas service had long been abandoned in America. Among practical men there never was any delusion that wooden steamers would be of lasting value in peace time service. As Chairman Hurley of the Shipping Board stated: "It was not contended by any responsible authority that wood ships would prove commercially advantageous, that they would be formidable competitors with the ships of the maritime powers in time of peace; but they were regarded, at least as far as the subsequent development of the wood ship programme was concerned, as mere war emergency ships." It should be borne in mind also that when these wooden steamers were contracted for a war lasting for years was contemplated as possible, and elaborate general preparations were being made to that end. As a matter of fact few wooden steamers were completed in time to carry supplies before the signing of the Armistice, and most of the wooden craft that did get to sea were laid up as soon as possible. Many of them seemed structurally fit, but their cargo capacity was too small to permit of profitable employment. The Emergency Fleet Corp. built more of the relatively small steel ships than could be absorbed by the requirements of normal commerce. Justification for this is to be found in the inexorable needs of war. These small steel steamers of from 3,500 to 5,000 dead-weight tons are of a type

very useful in limited numbers in a near-by trade, like that with the West Indies, for example. Some of them, particularly the oil-burners, are capable of engaging advantageously in trans-oceanic trades. Moreover, no steamers more than 260 feet in length and of about 4,000 tons dead-weight capacity could be brought out into the St. Lawrence River and the Atlantic through the Canadian canals, and it was important in the war months that the Great Lakes shipyards should be utilized.

American commerce, coastwise and overseas, is relatively a trade of rather large cargoes. It is the larger ship, with the lowest crew wage cost per ton, which American shipowners can operate to the best advantage. Nevertheless, these prudential considerations were frankly cast aside by the American Government in the crisis of the war. The authorities deliberately planned and built the kind of a merchant fleet that could be most quickly constructed in the greatest numbers and employed to the best advantage of their Allies.

After the War.—On the signing of the Armistice immediate steps were taken by the Shipping Board to reduce its programme of construction. In most cases where a contract could be cancelled at a cost to the Government less than the difference between the cost to complete and the probable market value of the ship at time of completion, cancellation was ordered. By June 30 1920 the building programme of the Shipping Board, which in Oct. 1918 had totalled 3,115 vessels of 17,276,318 dead-weight tons, was reduced to 2,315 vessels of 13,675,711 tons, of which 1,696 vessels of 11,656,961 tons were of steel construction. An important element of the new fleet not cancelled consisted of 23 passenger and cargo steamers of about 13,000 tons each, which were designed as army transports but have been adapted to commercial use. This class of ships, of which the American merchant marine still had too few, is adapted to service across the Atlantic and Pacific and to South America.

Appropriations for the Emergency Fleet Corp. up to the end of the fiscal year 1920 amounted to the immense sum of \$3,255,413,024, of which nearly all was expended for shipbuilding in the war emergency and afterward. Government-built steamers cost on the average \$200 to \$225 per dead-weight ton. Ships of the same type were built in the United States before the war for from \$60 to \$70 per ton, as compared with \$40 to \$60 in the United Kingdom. The record of America's war effort is clearly written in the returns of the Commissioner of Navigation of the total gross tonnage of shipbuilding in the United States in the fiscal years from 1915 to 1920 inclusive:—

Year	Gross Tonnage Built
1915	225,122
1916	325,413
1917	664,479
1918	1,300,868
1919	3,326,621
1920	3,880,639

In 1920 a marked decline in shipbuilding set in as the Government war programme approached completion. On March 1 1921 only 330 steel vessels of a total gross tonnage of 1,434,000 tons were on the ways. More than one-half of this tonnage was of tank oil carriers. Fifty-four of the 330 vessels, representing 435,000 tons, were building on Government account, and 276, of 999,000 tons, for private ownership. This sharp decrease in shipbuilding was then manifest all over the world, and was intensified by the shrinkage of trade and the unprecedented fall of ocean freight rates, which characterized the winter of 1920-1.

Manning and Operation.—Far less formidable than the task of creating new shipyards and building 13,000,000 dead-weight tons of ships for the war emergency was the work of officering, manning and operating these vessels. In the existing merchant marine of the United States, in Aug. 1914, there was a trained personnel of about 86,000, only a small part of whom could be spared for the new overseas services which the war demanded. Moreover, many of the trained American officers were required at once in the navy and the naval reserve. Two steps were promptly taken to meet the crisis; the President, by executive order July 3 1917, suspended the provision that watch-officers of vessels of the United States registered for the foreign trade must be American citizens, and the Shipping Board established an extensive sea recruiting and training bureau for the instruc-

on of both officers and men. Many who had followed the sea in their youth and had left it now returned, and new recruits appeared in great numbers. From June 30 1917 to June 30 1920 his service produced 9,642 licensed officers and 31,335 men, all American citizens. Many others who did not pass through the training service also joined the new ships, and wherever there was need officers and men were ordered from the navy personnel, which had reached a total strength of 500,000. Few ships were anywhere seriously delayed for lack of crews.

For the control of the new Shipping Board tonnage a division of operation was developed. Relatively few of the new vessels were directly operated by the Board itself. Most of them were placed in the hands of the established private companies or new concerns which the war had brought into existence. The vessels were placed on routes indicated by the Shipping Board. Their freight rates were controlled by the Board during and for some months after the war. Division of expenses and profits was difficult to arrange, and was long the cause of much friction between private operators and the Government. Not until 1920 was a fairly satisfactory plan finally devised by which the Shipping Board assumed the risk of the voyage, and a fixed percentage of the gross receipts was allowed to the manager for his services. Government ownership and operation of shipping, especially in the stress of war, proved a difficult undertaking in the United States, as elsewhere. Particularly important was the work of the Ship Control Committee, which directed the movements of shipping to the best advantage. This committee was composed of President P. A. S. Franklin of the International Mercantile Marine Co., President H. H. Raymond of the American Steamship Owners' Association, and Sir Connop Guthrie, representing the British Government.

At the signing of the Armistice, Nov. 11 1918, the Shipping Board controlled a total fleet of 1,196 vessels of 6,540,205 deadweight tons, composed of American, requisitioned, chartered, neutral and seized German tonnage. On Aug. 3 1917 the President, under authority bestowed by an Act of June 15, requisitioned for the national service all steel hulls and materials in American shipyards of vessels of over 2,500 deadweight tons, building either for American or foreign owners, a total of 431 vessels, of 3,056,000 deadweight tons. On Oct. 12 1917, as a further step in Federal control of the shipping situation, another executive order requisitioned all American steel-built power-driven cargo vessels of 2,500 deadweight tons and over, and all American passenger vessels of 2,500 gross tons and over fit for overseas service. This established control over an American fleet of 444 vessels of 2,938,758 deadweight tons. Many of these ships were transferred to their owners for operation. Others were chartered to the war and navy departments. About 600,000 tons of German vessels, seized in American ports when the United States entered the war, were divided among the Shipping Board and the army and navy. In addition the Shipping Board secured the use of a considerable fleet of enemy vessels seized in waters of other countries. To obtain an adequate amount of tonnage the Board also chartered many Allied and neutral ships, a resource which on Sept. 1 1918 amounted to 331 ships of a deadweight tonnage of 1,084,986. By order of March 20 1918, an act which though necessary was deeply regretted at the time, the President caused the navy to seize for the use of the United States 87 Dutch vessels of 533,746 deadweight tons, at that time in or bound to American waters.

A little more than one-half of the two and one-quarter million American soldiers sent to Europe were conveyed in the passenger steamers of Great Britain, France and Italy, chiefly in large vessels of the British lines. Most of the soldiers sent over under the American flag were borne in the former German liners that had had their damaged machinery repaired. After the Armistice, however, most of the American troops were repatriated under the colours of their own country.

The La Follette Law.—In the years from 1915 to 1920 inclusive there were several important Federal enactments relative to the merchant marine. One of these was the La Follette Seamen's Law, approved March 4 1915, after a long and bitter controversy in the House and Senate. This law to a large extent governs working conditions on American ships at sea and in harbour. It requires a certain fixed proportion of able seamen and certificated lifeboatmen, a complement of boats and rafts sufficient for all passengers and crew, and improved living spaces and sanitary conditions. Most of the Act in fact deals with life-saving methods and appliances, in accordance with the recommendations of the London Conference on safety of life at sea, following the "Titanic" disaster. Several sections require a more humane discipline than had been frequent in the old days. One section, which has been the cause of much displeasure among the foreign shipping companies, brought about the amendment of treaties requiring the U.S. Government to seize and return to their ships

seamen deserting from foreign vessels in American waters. This, and a complementary section permitting seamen of American or foreign vessels to demand at every port the payment of one-half of the wages due to them, once every five days, is charged with promoting the desertion of foreign crews in American waters and of burdening foreign companies with the cost of hiring substitutes at the American wage rate and with the expense of returning these substitutes to their country. It is insisted by the seamen's unions, however, that these provisions of the law tend to bring foreign ship wages up to American standards.

Other Legislation.—By Act of Congress of Aug. 18 1914 the free ship clause of the Panama Canal Act of Aug. 24 1912, which had proved wholly ineffective, was amended by admitting ships more than five years old, and exempting all foreign-built vessels admitted to American registry from compliance with American survey, inspection and measurement laws and regulations. Under this amended law 140 foreign-built vessels of 583,000 gross tons, owned by American citizens or corporations, were admitted to American registry for foreign trade in the fiscal year 1915, when the security afforded by the American flag was valuable. The number of vessels thus admitted fell off, however, to only 26, of 69,697 tons, in the fiscal year 1916, as the higher wages and operating costs of the American flag came to be realized by the owners of foreign-built tonnage. Many of these owners, indeed, sought to change their naturalized ships back to foreign registry, and 160 American vessels, of 102,479 tons, were transferred to foreign flags in 1916. On Feb. 5 1917 the President by executive order forbade the sale, lease or charter of American vessels to foreign flags without the approval of the Shipping Board.

In the spring of 1920 a most important measure known as the Merchant Marine Act of 1920, or the Jones law (from Senator Wesley L. Jones, Chairman of the Committee on Commerce), was finally passed by large majorities in Congress and signed June 5 by President Wilson. This Act solemnly declared it to be the purpose of the American people to possess a merchant marine capable of carrying "the greater portion" of their commerce and to serve as a naval or military auxiliary in time of war, this merchant marine "ultimately to be owned and operated privately by citizens of the United States." A new Shipping Board of seven members, fairly representative of political parties and of all sections of the country, was authorized in the Act and given large authority over the merchant marine. This Board was directed to sell the Government-owned tonnage to private owners "as soon as practicable." Postal subsidies and encouragement to new and necessary shipping routes were provided. Deferred rebates and discrimination against shippers were forbidden. The coastwise law barring foreign ships was extended after Feb. 1 1922 to the trade between the Philippines and the United States. Benefit of preferentially low railway rates on imports and exports was reserved to American vessels wherever their capacity is sufficient. Encouragement was given to American marine insurance, and to the American Bureau of Shipping, the "American Lloyd's." A new and favourable system of ship mortgages was provided. American vessels in foreign trade were exempted from excess profits taxes on condition that the amount of the exemption and twice as much more of the capital of the owners were applied to the building of other ships in the United States. The President was directed to secure the amendment of provisions in commercial treaties that prevented the United States from imposing discriminating customs taxes and tonnage dues on goods imported in ships of foreign registry. President Wilson refused to carry out this last-named requirement on the ground that the action indicated would provoke the resentment of foreign ship-owners and their Governments. The Treasury Department failed to prepare regulations for the application of the clause exempting American foreign-trade ships from excess profits taxes. Preferential treatment for American ships in the dispatch of imports and exports hauled at low rates on American railways was not made effective by the Shipping Board and the Interstate Commerce Commission, whose cooperation was necessary for the actual enforcement of the law.

Statistics.—The amount of shipbuilding, the total registered overseas and coastwise tonnage, the total merchant marine, and the proportion of American imports and exports conveyed in American ships for the six fiscal years ending June 30 1920 are as follows:—

Year	Ship-building	Registered for Foreign Trade	Enrolled or Licensed for Coastwise Trade	Total Merchant Marine	Proportion of Value of Imports and Exports Carried in American Ships
	Gross tons	Gross tons	Gross tons	Gross tons	Per cent
1915	225,122	1,862,714	6,486,384	8,389,429	14.3
1916	325,413	2,185,008	6,244,550	8,469,649	16.3
1917	664,479	2,442,776	6,392,583	8,871,037	18.6
1918	1,300,868	3,399,813	6,282,474	9,924,518	21.9
1919	3,326,624	6,666,376	6,204,426	12,907,300	27.8
1920	3,880,630	9,924,694	6,352,266	16,324,024	42.7

A new Shipping Board, appointed in June 1921, by President Harding, headed by Albert D. Lasker of Chicago and including Admiral William S. Benson in its membership, quickly effected an important reorganization of the executives of the Board, installing a group of practical shipping men as officials of the Emergency Fleet Corporation, and committing to these men the active management of the government-owned merchant fleet. Following this reorganization, the new Shipping Board addressed itself to the working out of a comprehensive subsidy system for postal liners and cargo ships, intended to facilitate the sale of the government-owned fleet to private owners, as directed by the Merchant Marine Act of 1920.

(W. L. M.)

SHOCK, in surgery (*see* 24.991*)—Experience during the World War has thrown new light on the nature of "shock" in pathology. The first effect of an injury is usually to produce a state resembling that of fainting. This is clearly produced through the nervous system and is recovered from more or less rapidly, supposing that the injury is not in itself sufficiently severe to be fatal. This "primary shock," as it may be called, does not show itself to any important degree in the case of operations done under an anaesthetic. But it has long been familiar to surgeons that another kind of shock may appear during or after an operation. This "secondary shock" was of frequent occurrence during the war of 1914-8 and the cause of many deaths. To define it, Cowell suggested the name "wound-shock." The symptoms are very difficult to distinguish from those of mere loss of blood, but it became obvious that it might be present although actual haemorrhage had been very slight. This fact is of significance in the interpretation of the actual pathology of the condition, as will be seen later. As indicated above, it does not show itself at once; it may, however, develop in less than an hour if the injury has been great, and primary shock may sometimes pass into it gradually without a period of recovery. It shows itself by a state of general collapse, with pallor, coldness, thirst, low blood pressure and the various consequences of this, such as vomiting, sweating and sometimes rapid shallow breathing. No evidence of heart failure or of paralysis of vasomotor centres has been obtained. The higher nerve-centres do not suffer until the late stages. Pain is not a prominent factor. If the state has not been of long duration nor of severe intensity, it may pass off on warming and rest, but if left alone death nearly always ensues.

Observations made by Sir Cuthbert Wallace in operations before the war suggested to him that the actual injury to the tissues, and especially to muscle, played an important part. This surgeon noticed that operations involving much section or removal of tissues were more liable to produce shock. The fact might, of course, be also interpreted as the result of the irritation of nerves, acting subconsciously on the centres; but Quénu, a French surgeon, at an early date in the war, propounded the view that the serious effects of wounds are due to an absorption into the blood of toxic products arising in the injured cells. This view was confirmed by the recognition of the importance of early removal of the injured parts; operative procedure was pushed nearer and nearer to the fighting line as the war progressed. It was also noticed that, even after shock had developed, a marked improvement was frequently brought about by excision of the damaged structures. Experimental work by Bayliss and Cannon showed that it was possible to produce in anaesthetized cats a condition similar to that of wound-shock. This could be done by extensive injury to the muscles and skin of the legs. It was found that the results were identical whether the nerve channels from the injured tissues were severed or not, but that they were absent if the blood returning from the tissue was prevented from passing into the general circulation. Thus the name "traumatic toxæmia," proposed by Quénu, is an appropriate descriptive title for the state under consideration.

But what is the nature of the poison and how does it act? These are important questions in dealing with appropriate methods of treatment. The possibility of bacterial toxins has been definitely excluded, and although it cannot be stated that we have yet found the actual substance produced in wounded tissues, the work of Dale and his colleagues on the properties of a base called "histamine," which is formed by removal of carbon

dioxide from one of the component amino-acids found in the proteins of tissues, namely histidine, shows that we have to deal either with this compound or with a very closely related one.

Dale and Laidlaw found, in fact, that a small amount of histamine injected into the veins of cats or dogs produced a large fall of blood pressure, accompanied by the other signs of shock, which increased progressively until death. The heart was unaffected and continued to beat powerfully, although nearly empty of blood. Now, until the work of Dale and Richards, it was believed that to produce a fall of blood pressure without removal of blood or depressing the heart it was necessary that the muscular coat of the arterioles should be relaxed and thereby the peripheral resistance decreased. But the previous work had shown that histamine has the effect of causing contraction of all smooth muscle, including that of the arterioles. The fall of pressure produced by a very small dose of histamine remained a paradox until the work mentioned, which was published in 1918. In this research it was shown that the effect was due to a wide-spread dilatation of the capillary blood vessels. In order to appreciate the significance of this discovery, a few words are necessary on the reactions of the capillaries and on the importance of the volume of blood in circulation. Although various observations had been made indicating that the capillaries are not merely inert channels, but that their walls are capable of contraction and dilatation in response to chemical stimulation or nervous influence, there seemed to be difficulty in realizing how protoplasmic cells such as those of the capillary wall succeed in doing this. The changes of shape in amoeba and in pigment cells, nevertheless, show the possibility. Dale and Richards, by an ingenious series of experiments, demonstrated that histamine does actually cause a marked widening and opening-up of the capillaries of the body generally. It may also be pointed out that Krogh has recently shown the existence of a nervous regulation of these vessels, which appears to be of an antidromic nature, like that of the dorsal roots described by Bayliss. Now, when we observe how enormous a share of the total vascular system the capillaries make up, we realize what a large volume of the total circulating blood may be penned up or pooled in these vessels when they are dilated, leaving very little to be sent round by the heart to supply the organs with oxygen obtained by its flow through the lungs. The whole of the body is therefore suffering from want of fresh blood containing the oxygen necessary for its existence.

These facts have caused renewed attention to be paid to the question of the volume of blood in circulation. By the injection into a vein of an innocuous dye, which does not quickly diffuse out of the blood vessels, such as "vital-red" or better "congo-red" (Harris), the degree of dilution of the amount injected indicates the volume of the fluid part of the blood. When observations of this kind were made by N. M. Keith on men suffering from shock, it was found that, even when they had lost little or no blood, the volume actually in circulation was greatly reduced. Hence we are justified in postulating the presence of a toxic action dilating capillaries, an action similar to that of histamine.

It was early recognized that shock might be greatly exaggerated or even brought on by various conditions incidental to the state of the wounded man, or to the treatment necessary afterwards. Some of these throw additional light on the subject.

Anaesthetics.—Dale observed that a dose of histamine highly toxic to a cat under ether was innocuous to a normal animal. Thus there are processes in the healthy organism which either destroy the poison rapidly but are inactive under ether, or the anaesthetic itself makes the capillaries more sensitive. In any case, it was often noticed in the war that a state of shock came on during an operation under ether and that there was less risk with nitrous-oxide and oxygen.

Haemorrhage.—Since the serious nature of shock is due to the deficiency of circulating blood, it is obvious that when blood has actually been lost a lesser degree of capillary stasis will suffice to induce shock. This was also found to be the case, experimentally, by Dale and by Bayliss and Cannon. A practical conclusion as regards operations seems to be that loss of blood should be avoided as far as possible and that means for replacing it by intravenous injection should be at hand in case shock makes its appearance.

Thirst.—There was always a notable demand for water by the wounded soldier. If he was already suffering from thirst when

* These figures indicate the volume and page number of the previous article.

wounded, his blood volume was diminished. Water is a valuable remedy and, as absorbed from the alimentary canal, it is very effective in restoring the blood volume. As we shall see, it is the actual volume of the blood, rather than its dilution, that is of consequence. Unfortunately, the vomiting frequently present in shock prevents this treatment in many cases. Water or saline solution may, however, be given by the rectum.

Cold.—Exposure to cold has a very potent exaggerating effect in shock. It may happen that spontaneous recovery takes place in the comparative comfort of the casualty clearing station, but, for the reason to be given below, it is not well to wait long if no sign of improvement is seen in a short time. It is difficult to give precise reasons why cold is so markedly deleterious. It may be the result of the generally depressing effect on all bodily functions, which would naturally be greater in states of inadequate circulation of blood.

Anxiety and Fear are recognized also as predisposing factors of shock. Perhaps the depressing effect is the cause, as with cold.

Treatment.—Since the cause of the trouble is the deficiency of blood in circulation, it is obvious that the chief remedy is to increase this. Much attention was given during the war to improving the methods of transfusing blood and there seems no doubt that many lives were saved by this means. But donors are not always available and it is clearly a matter of importance to possess, if possible, an artificial solution which can be used in unlimited amount. Simple saline or glucose solutions were soon found to be useless. They disappear from the blood in less than an hour. To prevent this disappearance, it is necessary to add to the solution some colloid which has an osmotic pressure equal to that of the colloids in normal blood. This is done in the "gum-saline" introduced by Bayliss. The solution contains 6% or 7% of pure gum arabic in addition to 0.9% sodium chloride. The reason for the addition of the colloid may be stated thus: the blood-vessels are impermeable to colloids, hence the osmotic pressure of these substances can manifest its effects. The important point is that it causes an attraction of water and thus prevents any rapid filtration by the blood pressure on the arterial side and brings about a reabsorption in the capillary and venous regions, where the blood pressure is lower than the osmotic pressure of the colloid. Thus a solution containing a sufficient amount of gum arabic is not lost from the circulation.

Of course, the blood actually in circulation is diluted by such injections, but the work of Gesell shows that the greater flow more than compensates for the lesser oxygen-carrying capacity per unit volume. Moreover, as the circulation improves, the capillaries begin to give up their stationary corpuscles to the general mass of blood.

When the state of shock is complicated by haemorrhage it might seem that the addition of blood itself is imperative. It is remarkable, however, that in actual experience the benefit of gum-saline was more obvious after haemorrhage than in severe cases of wound-shock without haemorrhage. It seems probable that these latter cases were such as to have arrived at that stage in which a second action of histamine shows itself. To this we may now turn. After large doses or prolonged action of smaller ones, the capillary blood-vessels become permeable to the colloids of blood as well as to the salts. The addition of solutions of colloids or even blood itself is useless in this stage. They are quickly lost. It was found by observations on wounded men that the plasma of the blood transfused was lost rapidly. Whether the effect on the capillaries is a direct one or whether it is due to the asphyxial state brought about by the low blood pressure is not clear at present. Krogh brings evidence that, when the capillaries are rapidly and widely dilated, there may be formed minute pores between the cells of their walls, which allow colloids to pass through. The fact warns us, in any case, not to allow the state of low blood pressure to last for any length of time.

Cases of shock in this stage were generally regarded as hopeless. It was not found possible to restore them either by blood or by gum-saline. Some experiments made later by Bayliss suggest, however, the possibility that further repeated injections might in some cases have been effective. Although the greater part of the fluid of the first injection was lost, it seemed that some improvement in the state of the capillaries resulted, since a second injection produced a slight permanent rise in the blood pressure and a third injection recovery.

Owing to the fact that gum-saline is quite innocuous and can now be obtained in sterilized form from the dealers, it should always be at hand in operations for use if shock threatens, as also for accidents or serious haemorrhage from any cause.

See *Special Reports*, Nos. 25, 26, 27, *Medical Research Council* (London H.M. Stationery Office, 1919); E. Quénu, *La Toxémie traumatique* (Paris, Alcan, 1919); Bayliss, *Intravenous Injections in Wound-Shock* (London, 1918). (W. M. B.)

SHORT, SIR FRANCIS JOB (1857—), English engraver (see 24.1007), was elected R.A. in 1911, and in the same year was knighted. In 1910 he became president of the Royal Society of Painters, Etchers and Engravers. His later work exemplifies every type of his activity. Among etchings, "On the Banks of the Bure" and "The White Mill, Canterbury" show his adherence to the use of line in that medium, and a version of Turner's "Ehrenbreitstein to Coblenz" continues his series of translations of paintings. He also added "Moonlight on the Medway at Chatham" and "Dumbarton Rock" to the plates in etching and mezzotint completing Turner's "Liber Studiorum." Two aquatints, "The New Moon" (1918) and "Twixt Dawn and Day," show broad handling and remarkably rich quality in the darks; and two mezzotints, "Orion over the Thames" (1913-4) and "The Night Picket Boat at Hammersmith" (1914-5), are among his finest plates in a medium peculiarly his own.

SHORTER, DORA (Sigerson) (1866-1918), Irish poet, was born in Dublin, Aug. 16 1866. She was the daughter of Dr. George Sigerson, the Celtic scholar, and married in 1896 Clement K. Shorter (b. 1857), editor of the *Sphere* and other London illustrated papers (see 19.563). Her first volume of verse appeared in 1894, and she established a considerable reputation as a writer of lyrics and ballads; the subjects often religious, or drawn from the treasures of Irish legend, or in praise of the Irish country. Her *Collected Poems* were published in 1909, and she wrote one novel, *Through Wintry Terrors* (1907). She died in London, Jan. 6 1918. Two posthumous volumes of poems appeared in 1918 and 1919, as well as *A Dull Day in London and other sketches*, with a preface by Thomas Hardy, in 1920.

SHORTT, EDWARD (1862—), British lawyer and politician, was born at St. Anthony's Hall, Newcastle-on-Tyne, March 10 1862. He was educated at Durham school and University, and in 1890 was called to the bar. In 1907 he became recorder of Sunderland and in 1910 a K.C. In 1910 he entered the House of Commons as Liberal member for Newcastle. In May 1918 he became Chief Secretary for Ireland, but in 1919 resigned and was appointed Home Secretary.

SIAM (see 25.2).—For the purposes of administration the kingdom of Siam is divided into 17 provinces (Monthon), the area of which is given officially at 484,128 sq. kilometres. The revised census figures for 1910-1 gave a pop. of 8,149,847, and the official estimate of the pop. for the year 1920 was 9,022,000.

On the death in 1920 of King Chulalongkorn he was succeeded by his son, the Crown Prince Maha Vajiravudh, who in 1917 assumed the title of King Rama VI. Under this monarch the work of consolidation and development progressed steadily. To foster the idea of the duty of national service among the elder generation the "Wild Tiger" Corps was established. The Siamese boy scout organization, of which the King became president, educates the younger generation on the same lines. The number of boy scouts was in 1920 over 15,000.

Among various changes may be noted the royal decree that all privy purse property should be subjected to ordinary taxation, the abolition of lottery farms and public gambling-houses, the strict regulation of the opium traffic, and the great development of football and other athletic sports. Under the patronage of the King, a Navy League was established, and the Red Cross Society was reorganized. The Red Cross Society has under its direction the Chulalongkorn hospital, the Pasteur institute and laboratories for the preparation of vaccines and serums.

The calendar has been revised. The Siamese year formerly dated from the foundation of Bangkok. It now corresponds with the Buddhist era. The new year begins on April 1 and terminates on March 31. Hence April 1921 to March 1922 is, in the Siamese calendar, B.E. 2464. The day is divided into two periods of 12 hours each as in Europe, except in the railways and the post and telegraph department, where the 24-hour day is used.

On July 22 1917 Siam declared war on Germany and Austria-Hungary. Enemy aliens were interned, and later sent to internment camps in India. A military mission was sent to Europe early in 1918, and a Siamese military contingent landed at Marseilles in Aug. of the same year. This contingent comprised motor ambulance transport, which rendered efficient service on the western front, and an aviation corps. The aviators were trained by French officers, and although many had gained pilot's certificates, hostilities ceased before the corps was prepared to commence operations. The contingent returned to Siam in 1919. Siam was represented at the Versailles Peace Conference by three delegates, who signed the general Peace Treaty on behalf of their country.

The main clauses affecting Siam are Articles 135, 136 and 137. In Article 135 Germany recognizes that all treaties, conventions and agreements between her and Siam, and all rights, titles and privileges derived therefrom, including all rights of extra-territorial jurisdiction, terminated as from July 22 1917. In Article 136 all goods and property in Siam belonging to the German Empire or to any German State, with the exception of premises used as diplomatic or consular residences or offices, pass *ipso facto* and without compensation to the Siamese Government, while the goods, property and private rights of German nationals in Siam shall be dealt with in accordance with the provisions of Part X (Economic Clauses) of the Treaty. By Article 137 Germany waives all claims against the Siamese Government on behalf of herself or her nationals arising out of the seizure or condemnation of German ships, the liquidation of German property, or the internment of German nationals in Siam, this provision not to affect the rights of the parties interested in the proceeds of any such liquidation, as governed by the provisions of Part X (Economic Clauses) of the Treaty. Under the Treaty Siam became a member of the League of Nations, and took part in the first Assembly of the League at Geneva in 1920.

Agriculture.—Owing to deficient rainfall in 1919, rice, the main agricultural crop of Siam, was barely sufficient to supply the needs of the population, and the price rose to five times pre-war rates. To meet the deficiency the export was prohibited, but was resumed in 1921. The question of extensive irrigation works, which had been considered in the previous reign, was again investigated in 1915, and important works were started. The difficulty of obtaining steel work from abroad during the war delayed their progress, but work on the Prasak scheme, estimated to cost some 13,000,000 ticals, was afterwards vigorously pushed forward, and was expected to be completed in 1922.

Army and Navy.—The law of 1903 making military service compulsory was revised in 1917. Every able-bodied man of 21 to 22 years of age is liable to be called to military service for a period of two years with the colours, passing afterwards into the reserve, of which there are three classes according to age. There are various military schools for the training of officers, non-commissioned officers, aviators, military engineers, etc., as well as a General Staff school. The arms and equipment are modern, and in 1914 a national cartridge factory was established. The navy is recruited from the maritime population under the military service law. There are some 5,000 men available for service afloat, with a reserve of 20,000. In 1920 a 35-knot destroyer was purchased from the British Admiralty and rechristened the "Phra Ruang."

Communications.—On the declaration of war the northern and southern State railways were amalgamated under a Commissioner-General, H.R.H. Prince Purachatra of Kambang Bejra. The personnel, which had included German engineers, became chiefly Siamese, with a few engineers of Allied nationality. A standard metre gauge was adopted for all lines. The southern line through the Malay Peninsula was originally constructed of metre gauge to permit of through connexion with the Federated Malay States railways. The work of converting the northern line, first built to the normal gauge of 4 ft. 8½ in., was begun. A through service of trains from Penang to Bangkok was opened on the southern line in 1918, and in March 1920 railhead reached the Siam-Kelantan boundary. The northern line reached Chiangmai in 1920, and the Bandara-Swankatok branch was then under construction. The length of State lines in 1920 was: opened 2,215 km., under construction 211 km., and under survey 460 km. The average capital cost per km. of open line was tcs. 54,584.

Education.—There were in 1920 over 380,000 pupils receiving primary education, of whom 250,000 were being educated by priests in the Buddhist monasteries, 100,000 in local and private schools, and 30,000 in schools directly under the Ministry of Education. Secondary education, reaching a standard approximating to that of the London University Matriculation, is provided for by the Ministry of Education, with 120 schools attended by 8,500 pupils, by the two Royal Pages' schools and King's College, under the direct patronage of the King, and by certain missionary schools. In 1917 the Chulalongkorn University was opened at Bangkok with four Faculties—Medicine, Arts and Science, Engineering and Political Science. It includes hostels for 100 resident undergraduates.

Finance.—Annual revenue rose from tcs. 17,334,469 in B.E. 2437 (1894-5) to tcs. 86,494,066 in B.E. 2460 (1917-8). During this period the expenditure increased from tcs. 12,847,165 to tcs. 74,149,728. The national debt consisted in 1921 of two sterling loans both of 4½%, one for £1,000,000 floated in 1905, and one for £3,000,000 floated in 1907, both free of taxes present or future, levied by the Siamese Government and repayable by yearly drawings. The 1905 loan will be entirely paid off in 1945, and the 1907 loan in 1947. In 1909 a loan of £4,000,000, increased in 1913 to £4,750,000, was negotiated with the Federated Malay States Government. This loan is exclusively for constructing railways in the Malay Peninsula, the amount advanced is limited to £750,000 in any one year, and interest is at the rate of 4% on the money actually received. The amount actually advanced on this account to March 31 1921 was £3,880,000, when the total debt of the kingdom stood at £7,312,560.

The mint was closed to the free coinage of silver in 1902, and, supported by the Treasury, exchange had steadied to around tcs. 13 to the pound sterling by 1909. In 1917 and 1918 the rate was maintained at tcs. 13.02 to the pound sterling, but by 1918 the Treasury had sold to the banks tcs. 77,000,000, representing nearly £6,000,000 sterling. As a result of these sales a large proportion of Treasury funds was transmitted abroad. The rise in the price of silver nearly denuded the country of silver coinage, and in 1920 the exchange rose to tcs. 10 to the pound sterling and over. The gold standard reserve fund, established for the maintenance of the gold value of the tical, remained untouched on March 31 1918 at £1,222,146.

Trade.—For 1917-8 the value of imports exceeded tcs. 97 million, including tcs. 3½ million of gold leaf and treasure. This shows an increase of some 10 millions over the previous year and 22 millions over 1915-6. The exports amounted to tcs. 123½ million, showing an increase over the previous year of tcs. 2 million and over 1915-6 of nearly tcs. 18 million. The value of rice exported was over tcs. 97½ million and of teak tcs. 5½ million.

Justice.—The Penal Code became law in 1908, and the preparation of other codes continues. All courts are under the Ministry of Justice. The judiciary is composed of native or European-trained Siamese judges, assisted in cases where foreigners are concerned by European legal advisers. In commercial cases where there is no Siamese statute or precedent customary law is administered. Where precedents are wanting the Siamese courts are guided generally by English statutes and cases as circumstances admit. On the outbreak of war with Germany and Austria a prize court was established to deal with enemy ships seized "*jure belli*." Twenty-five enemy vessels were taken, and condemned as lawful prize by this court.

Public Health.—Modern sanitation began in Siam in 1897 with the creation of a Public Health Department under a director-general, assisted by a medical officer of health and a city engineer. The principal developments have been the inspection of cattle and meat and the regulation of the public abattoirs under veterinary inspection, the establishment of infectious diseases hospitals, medical treatment of the insane, quarantine, registration of births and deaths, compulsory notification of plague and cerebro-spinal diseases, and compulsory vaccination and revaccination against smallpox. An efficient public-health laboratory has been organized under the department. Bangkok is now efficiently drained and lighted. Pure filtered water is supplied from the Government water works. New roads have been cut through congested districts, and numerous bridges have been built over the canals which intersect the city. On the outskirts new residential quarters have been laid out, with broad roads lined with trees. (A. C. CA.)

SIBELIUS, JEAN JULIUS CHRISTIAN (1865—), Finnish musical composer, was born at Tavastehus, Finland, Dec. 1865. He was educated at Helsingfors, and later studied music at Berlin and Vienna. In 1916 he became a professor of literature at Helsingfors. His orchestral works include "Romance in C" (1890); *Karelia* (1893); *Frühlingslied* (1893); *Finlandia* (1905) and five symphonies (1897, 1901, 1905, 1910, 1915). He also composed many songs and pianoforte pieces. His music to the tragedy *Kuolema* (1904) contains the "Valse triste," which has gained wide popularity. In 1921 he visited England and produced his 5th symphony.

SIBERIA (see 25.10).—The name Siberia now generally excludes the Steppe provinces but includes Kamchatka and Russian Sakhalin.

Little progress has been made in the mapping of the wide tracts between the great rivers or the mountainous regions in the south. Even in the existing maps of southern Siberia little reliance can be placed on the detail except near the railway. There are no large scale maps of northern Siberia. The whole course of the Yenisei river has been mapped on a large scale, the shores of Lake Baikal have been surveyed and geological exploration in the Amur basin and some parts of the upper Lena basin has resulted in accurate maps.

Kamchatka contains a notable range of volcanoes which forms part of the Pacific ring. Forty have been located of which 14 are active. The loftiest active volcano, the loftiest mountain in Siberia, is Klyuchevskaya, 16,130 feet. Koryatskaya is 11,522 feet.

Investigations in Lake Baikal have shown that there are three basins of unequal extent and depth. The southerly basin has an extreme depth of 791 fathoms, and is separated by a shoal ridge of less than 300 fathoms from the middle and most extensive basin which reaches 832 fathoms in depth. The northern basin does not exceed 540 fathoms. On the W. of the lake the deep water goes inshore but on the E. the coastal waters are shoal. The area of the lake is 13,200 sq. m.; its surface is 1,561 ft. above sea level.

New surveys of the Arctic coast by Tolmachev, Vilkitel and others have resulted in considerable modifications in the chart. Shitkov explored the Yamal peninsula and cleared up some doubtful points in its hydrography. The small islands between the Gulf of Yenisei and Taimir peninsula have proved to be more numerous than was supposed and Taimir Gulf has been found to be relatively narrow. Cape Chelyuskin lies in lat. 77° 42' N. Nikolas Land and other islands have been discovered to the N.W. of this cape, and new discoveries have been made in the New Siberia and Wrangel Is. (see ARCTIC REGIONS). There is still some doubt about the configuration of the coast-line between Cape Chelyuskin and the Lena delta. Hydrographical surveys have resulted in the discovery of some harbours on the Arctic coast including several in Taimir Land; Tiki Bay, E. of the Lena delta; and Chaun Bay in long. 170° E. Surveys in the Sea of Okhotsk have shown that the best harbours are Yamakaya Bay; Ola Bay, off Taiu Bay; and Port Ayan. Okhotsk is falling into decay owing to its poor site. In Kamchatka Baron Korfa-Gulf has been found to contain several good harbours. In the Maritime province the best harbours, in addition to Peter the Great Bay, are de Castries Bay, Imperial Bay and Olga Bay. De Castries Bay, a little S. of the Amur mouth, affords a far better and more accessible harbour than the Amur estuary. The Tartar harbours are closed by ice from Nov. to April or May and the Okhotsk harbours for a month or two longer.

Population.—There has been no census since 1897 but in 1915 the pop. was estimated at 10,377,000 on the basis of the last census and the yearly rate of increase. It was distributed as follows:—

Governments and Provinces ¹	Area in sq. m.	Population ²	Density per sq. m.
Tobolsk (Govt.) . . .	535,739	2,085,700	3.9
Tomsk (Govt.) . . .	327,173	4,053,700	12.0
Irkutsk (Govt.) . . .	280,429	821,800	2.5
Yeniseisk (Govt.) . . .	981,607	1,143,900	1.1
Yakutsk (prov.) . . .	1,530,253	332,600	0.2
Transbaikalia (prov.) . . .	238,308	971,700	4.0
Amur (prov.) . . .	154,795	261,500	1.6
Maritime or Primorsk (prov.) . . .	266,486	631,600	3.0
Kamchatka (prov.) . . .	502,424	41,600	0.1
Sakhalin (prov.) . . .	14,668	34,000	0.5
Total . . .	4,831,882	10,378,100	2.0

¹ These indicate the administrative divisions in force under the empire. The present (1921) divisions are uncertain and unstable.

² The pop. estimates are probably somewhat too high.

The two Steppe provinces, Akmolinsk and Semipalatinsk, which are geographically part of Siberia, though they were administratively distinct under the late imperial regime, have a combined area of 493,394 sq. m. and an estimated pop. (1915) of 2,421,400. The figures given above include native tribes (see below).

Colonization.—The Russians number over 85% of the total pop. of Siberia as a whole and about 93% of the total pop. of western Siberia (Tobolsk and Tomsk). The number of settlers entering Asiatic Russia (including the Steppe provinces) from Russia in Europe rose from 141,000 in 1906 to 619,000 in 1909. For some years after there was a decline, due, it is said, to a succession of good harvests in southern Russia: in 1912 and 1913 the annual immigration was little over 200,000. In 1914 it was 242,000. From 1906 to 1914 nearly 3,000,000 Russians entered Asiatic Russia, about 2,000,000 of whom went to Siberia. The Siberian railway zone continued to attract most settlers in western and central Siberia but many went to the Baraba steppe, the Altai region and the district round Minusinsk and the upper Yenisei. The Uryankhai region around the head streams of the Yenisei in the Sayansk mountains, which is nominally part of outer Mongolia under the suzerainty of China, contains many Russian settlers and for some years has been more or less under Russian control. In Transbaikalia much land is occupied by Cossacks and their descendants, and natives (largely Buryats), but in the upper Amur and the Ussuri valleys there are considerable areas of Russian settlement. The efforts, however, that were made by the State before 1917 to attract colonists to the Amur and Maritime provinces met with somewhat meagre response. Attempts to colonize Kamchatka have been practically abandoned and for many years Russian Sakhalin has failed to attract settlers.

North of lat. 58° N. in western Siberia, and lat. 54° N. in eastern Siberia; there are very few Russians permanently settled. Total exemption from military service and other privileges which the State offered colonists in the lower valleys of the Yenisei and Lena did not succeed in attracting many settlers. The migration of Chinese and Koreans to the Amur and Ussuri valleys and the Transbaikalia region was marked for many years. The Chinese came as temporary labourers but the Koreans were more inclined to become permanent settlers. Japanese artisans are found throughout eastern Siberia. In 1914 the Russian Government was making attempts to exclude Asiatics at the same time that it offered inducement to Russians to settle in the Far East.

Native Races.—While no strictly ethnological classification of Siberian natives is yet possible, it is recognized that the tribes of the extreme N. and E., even if they differ from one another, have certain characteristics in common which distinguish them from later arrivals in Siberia. For these earlier tribes, who may possibly have migrated to Siberia from America at a very early period, the name Palaeoasiatics is used by Schrenk and Palaeo-Siberian by Czaplicka. For later tribes the term Neo-Siberian has supplanted Ural-Altaians to which there are linguistic and ethnological objections. Czaplicka classifies the native tribes of Siberia as follows, taking numerical statistics from Patkanov, who based his estimates on the census of 1897 which gives the latest trustworthy data: i. Palaeo-Siberians. i. Chukchee; in north-eastern Siberia, 11,771. ii. Koryak; S. of the Chukchee, 7,335. iii. Kamchadal; southern part of Kamchatka, 2,805. iv. Ainu; in southern Sakhalin and Yezo, 1,457. v. Gilyak; near Amur mouth and in northern Sakhalin, 4,649. vi. Eskimo; shores of Bering Strait, 1,307 (in Asia). vii. Aleut; in Aleutian Is., 574. viii. Yukaghir; between the lower Yana and lower Kolima, 754. ix. Chuvany; S. of Chaun Bay, 453. x. Otyak of Yenisei; on the lower Yenisei, 988. ii. Neo-Siberians. i. Finnic tribes (a) Ugrian Otyak; lower and middle Ob, 17,221. (b) Vogul or Maniza; middle Ob, 7,476. ii. Samoyedic tribes; in far N. from Europe to Khatanga mouth, 12,502. iii. Turkic tribes (mainly outside Siberia) (a) Yakut; from the Lena to the Amur and Sakhalin, 226,739. (b) Turco-Tatars of Tobolsk and Tomsk, 176,124. iv. Mongolic tribes (a) Kalmuk or Eleut; practically all outside Siberia (b) Mongols proper or Kalkha, 402. (c) Buryat; around Lake Baikal, 288,599. v. Tungusic tribes (a) Tungus; far eastern Siberia, 62,068. (b) other Tungusic tribes, totalling 14,439, viz. Chapagir; on the lower Tunguska; Goldi; on the lower Amur; Lamut; on the shores of Sea of Okhotsk; Monagir; on the middle Amur; Oroche; E. of the lower Amur; Orochon; on the Olekma; Oroke; in Sakhalin; and Solon; S. of the middle Amur. Tribes who live in the more fertile parts seem to be increasing in numbers but those who occupy the more barren regions of the N. are dwindling. The natives probably do not exceed one million.

There is much disease, particularly among the native tribes, although the climate itself is not unhealthy. In addition to goitre, leprosy occurs in the Lena and Amur valleys and elsewhere. Smallpox is endemic in many parts and tuberculosis is prevalent. Cholera is never absent in the Far East and occasionally assumes the proportions of an epidemic. Plague sometimes enters from Manchuria. Venereal diseases are rampant throughout Siberia. A curious nervous affection known as Arctic hysteria is common among the natives of the far north. It is not infrequently associated with melancholia and suicide. The hysterical manifestation of Shamanism may not impossibly be associated with this nervous affliction.

Education.—The last statistics date from 1912 when there were 6,245 schools in Siberia with a total of 341,271 pupils. The number of pupils per 1,000 of the pop. was thirty-six. Out of every 100 persons under nine years of age only 16 could read and write.

Towns.—Towns situated on or near the railway have grown rapidly but others have made little or no progress. In 1914 towns with a pop. of 10,000 or over numbered at least 21 compared with 17 in 1900; but estimates of the pop. of Siberian towns vary considerably and must be accepted with reserve. The largest towns are Tomsk (112,000) and Irkutsk (113,000), the capitals of western and eastern Siberia respectively. Omsk (128,000) is really a Siberian town but actually within the Steppes. Other large towns in western Siberia are: Novo-Nikolaevsk (63,000), a centre of rapid growth situated where the Siberian railway crosses the Ob; Barnaul (52,000) and Biisk (28,000), both centres in the rich Altai region. Kurgan (35,000) on the Tobol, a great agricultural market; Tyumen (30,000) now on the railway and a focus for trade between Russia and Siberia; Tobolsk (21,000), a declining fur and fish market on the Irtysh; Kolivan (13,000) on the Ob, with agricultural interests; Mariinsk (13,000), a mining centre on the railway and Achinsk (10,000) a little farther east. In eastern Siberia other important towns are: the great port of Vladivostok (95,000); the two Amur ports and agricultural centres, Blagoveshchensk (76,000) and Khabarovsk (53,500); Chita (73,000) with growing agricultural and commercial interests; Krasnoyarsk (73,000), the chief river and railway port of the Yenisei; Nikolai-Ussuriyski (34,700), a rising industrial and railway centre 70 m. from Vladivostok; Nikolaevsk (12,500), the port at the Amur mouth; the two mining centres on the Yenisei, Minusinsk (14,000) with agricultural interests, and Yeniseisk (10,000); Kansk (10,000) on the upper Yenisei and Siberian railway; Stryetensk (10,000), at the head of the Amur-Shilka navi-

gation; and Verkhne-Udinsk (9,500), a railway and industrial centre in Transbaikalia. The towns of the far N. are small and primitive. Yakutsk, a fur-trading centre on the Lena, has a pop. of 8,200 and Verkhoyansk, on the Yana, only 450. The pop. of Sredne-Kolimsk, on the Kolima, which is the largest centre in the N.E. of Siberia, is 650. Petropavlovsk, the capital of Kamchatka, has fallen to some 500; Alexandrovsk, the capital of Russian Sakhalin, about 6,000, a figure, however, which includes more natives than Russians; and Okhotsk to less than three hundred.

Agriculture.—In western Siberia about 17,000 sq. m. are under crops (1913) but there are still great areas of natural grassland waiting for cultivation. In eastern Siberia agriculture has not made great progress except in the southern Ussuri plain: natural grasslands are scarce but there are many forest areas on the Amur which, if cleared, would afford good agricultural land. The area under crops in eastern Siberia is 2,800 sq. m. (1913). Agricultural methods in the W. have undergone some improvement, through the use of fertilizers and the importation of American agricultural machinery. Many flour-mills have been erected. Western Siberia sends its surplus wheat to Russia and eastern Siberia. The latter region also imports corn from Manchuria. In 1913 the total cereal production of Siberia was 68,200 cwt. and the average annual production (1908-13) was 50,200 cwt.

Land Tenure.—After the revolution of 1917 the State became the owner of all land in Siberia except some 5,000,000 ac. granted to Cossacks or other private persons. All other holders of land are tenants of the State, enjoying in some cases hereditary leases. The State ownership would seem to apply also to minerals, timber, fisheries and water power but some concessions have been recognized in favour of foreigners.

Live Stock.—The rearing of live stock has made more progress than agriculture. In 1913 the Steppe towns of Petropavlovsk and Omsk had become great centres for the export of meat to European Russia, drawing a large part of their supply from the Tomsk province. In the Transbaikal, Amur, and Maritime provinces cattle-breeding promises to attain greater importance than agriculture, but the meat supply of eastern Siberia is partly dependent on imports from Manchuria. The successful acclimatization of the merino sheep in central Siberia holds promise of much wool production in the Yeniseisk and Irkutsk provinces. Pig-breeding is a growing industry in western and central Siberia and by 1914 bacon exports had become important. Reindeer-breeding is the chief occupation of most of the far northern tribes. Maral deer and other species of wapiti are bred in the Altai, the Maritime province and elsewhere for their horns, which to the Chinese have a reputed medicinal value. The official figures (in round numbers) for the number of live stock in Siberia in 1911 and 1914 are as follows:—

	Horses	Horned cattle	Sheep and goats	Pigs
1911	4,598,000	5,719,000	5,250,000	1,126,000
1914	4,840,000	6,541,000	5,745,000	1,428,000

The dairy industry has developed quickly, fostered by State encouragement and the export facilities afforded by the railway. In 1912 there were 1,060 coöperative dairies in the Tobolsk province, and 2,042 in the Tomsk province. The export of butter from western Siberia reached 35,000 tons in 1903 and 76,000 tons in 1913; in the latter year the home consumption accounted for an additional 75,000 tons. The industry is of less importance in eastern Siberia.

Hunting.—The fur industry retains great importance and was much stimulated during the early years of the World War by the high price of skins. But decrease of game is causing hunting in many parts of the N. to take a secondary place to fishing and reindeer-breeding. The sable became so scarce that from 1913 to 1916 its slaughter was forbidden. The white fox is becoming rare. The principal fur fairs are at Irbit (Feb.) and Yakutsk (July), but Ishim, Blagoveshchensk, Nikolaevsk and Anyui are also frequented by traders in search of furs. Yakutsk has also a trade in fossil ivory from the New Siberia Is.: in 1913 nearly 20 tons were sold. In order to prevent their extermination the few seals of the Commander Is. were protected for five years from 1912.

Fishing.—In western Siberia the most important fisheries are on the Ob. Tobolsk is the headquarters of the industry: Obdorsk, Beresov, Surgut and Narim are also important centres. At least 10,000 men take part in the fishery and the annual catch is about 15,000 tons. On the upper Irtysh Pavlodar and Lake Zaisan are centres of fishing. The fisheries of the lower Yenisei send S. about 3,000 tons every year. In Lake Baikal there are valuable fisheries both in summer and, through the ice, in winter. In the Lena and Kolima regions the natives live chiefly on fish but lack of transport facilities prevents export. Fisheries in the Amur, Okhotsk and Kamchatka regions steadily increase in importance. The fish are mainly species of salmon but not the same as those in western Siberia. The fisheries are largely in Japanese hands but legislation in 1899 restricted to Russians all fisheries in the Amur and its estuary. In 1913 the mouths of certain rivers on the Okhotsk and Kamchatka coasts were closed to all fishing in order to conserve the fisheries. In 1913 the Okhotsk and Kamchatka fisheries resulted in a total catch of 46,000,000 salmon, most of which went to Japan.

Salmon caviar to the extent of 2,477 tons was exported from the same districts. Salmon-canning is a new industry: in 1913 the output from Kamchatka was over 500,000 tins, and from the lower Amur 100,000 tins. Attempts to send frozen fish from the Amur to Europe met with some success when begun in 1913. The fisheries of Russian Sakhalin are losing their importance. In the Sea of Japan the herring-fishing from Imperial and Peter the Great bays is growing in value.

Timber.—Siberian forests of commercial timber are estimated to cover about 470,000 sq. m. or about one-tenth of the total area of the country, but owing to absence of transport facilities only 150,000 sq. m. are considered to be exploitable. In western Siberia there is little trade in timber and the demands for home use and the havoc of forest fires are decreasing the available supply. The principal saw-mills are at Tobolsk, Tyumen, Omsk, Novo-Nikolaevsk and Tomsk. In eastern Siberia the timber industry is confined to the Amur and Maritime provinces except in respect of the demand for fuel for railway, industrial and domestic purposes. The principal saw-mills are at Irkutsk, Blagoveshchensk, Nikolaevsk, Imperial Bay, Vladivostok and Alexandrovsk (Sakhalin). Export is from Vladivostok, Imperial, Olgi and Posiet bays to Australia, the British Isles and Japan. Before the war great efforts were being made to encourage this trade.

Minerals.—Gold is the most important mineral in Siberia. The Lena drainage area, especially the valleys of the Olekma and Vitim, is considered to be the richest gold-producing area in the world. All the gold worked is alluvial and the annual yield (1916) was some 400,000 oz. Bodaibo, connected by rail to the Vitim, is the centre of the industry. The gold-fields of the Amur valley when fully explored will probably prove to be even greater in extent. The new town of Zeya Pristan on the Zeya is the principal mining centre on the middle Amur. The Bureya valley is also rich in gold. On the lower Amur there are rich gold-fields near Lake Chyla. The Amur gold is alluvial and most of it is very fine. British interests control the principal gold-fields of both the Lena and Amur basins. Gold is reported from several places on the Sea of Okhotsk, in the Chukchee peninsula and in the Anadir region. The output in Transbaikalia is falling off. In the Yeniseisk region there are valuable deposits in the Abakan valley. In western Siberia the gold output is declining but, as placer mining gives way to quartz crushing, shows prospect of reviving. Quartz veins are rich in the neighbourhood of Ust-Kamenogorsk and Lake Zaisan. The gold-bearing rocks in Siberia as a whole, including the Urals, are estimated to cover over 800,000 sq. miles. The total output of gold in 1913 was estimated at 1,500,000 oz., of which over 90% was from eastern Siberia; but there is reason to doubt the accuracy of official figures. In the same year the number of men employed in the gold industry in Siberia was 56,400. Climate, labour and transport, apart from political difficulties, afford obstacles in the development of the industry. The output of silver has shown a decline for many years, but numerous rich deposits are known to exist in the Altai region and around Nerchinsk. The production of zinc has increased, largely due to the rich Tyutikhina mines in the Priamur. Lead is obtained from these mines and also from the Altai mountains and Ust Orinskaya on the Lena. Zinc and lead mines at Riderski in the Altai are linked to the Irtysh by a 70-m. narrow-gauge railway. Tin occurs in the Onon valley in Transbaikalia, but it is little worked. New deposits of graphite have been reported from Cape Dezhneva on Bering Strait. Copper occurs mainly in the Urals and in the Karkaralinsk district of the Kirghiz steppes, both of which regions are outside Siberia proper. There has been little if any progress in the production of iron except in the Urals, but valuable deposits of iron ore are reported in the Amgun valley near the Amur mouth, in the vicinity of Vladimur and Olgi Bays in the Priamur, in many parts of the Altai and near Karkaralinsk in the Steppes. Considerable coal deposits of varying quality have been located, but comparatively few are mined. Want of markets and transport facilities are drawbacks even where the coal is of good quality. The most promising deposits are the Kuznetak beds in the Altai region which contain coking coal; beds around Cherekhovskoe, 70 m. W. of Irkutsk, where some 5,000,000 tons of lignitic coal are mined annually, principally for use on the railway; the Suchan mines, 60 m. from America Bay, on the Sea of Japan, and the Mongugai beds near Amur Bay on the Tartary coast. The Mongugai beds and those at Due in Sakhalin both consist of good anthracitic coal but neither is seriously worked. Coal in the Amur and Lena valleys and Transbaikalia is chiefly lignitic. There are large deposits of lignite at Baron Korfa Gulf in Kamchatka. In the Kirghiz steppe coking coal is worked at Ekibastuse. The mines, which are controlled by a British company, are connected with the Irtysh at Yermak by a railway 70 m. in length. Petroleum-bearing strata exist on the eastern shores of Lake Baikal and near Nabitski Bay in Sakhalin, but the oil is not exploited.

Manufactures.—Manufactures on a large scale have made little progress except in engineering works and repair shops for the railways. The competition of the Ural iron foundries, which have better transport facilities, has adversely affected the Siberian foundries, but a few persist, notably at Petrovsk in Transbaikalia, Blagoveshchensk and Tyumen. At Ekibastuse in the Steppes the zinc and lead ores from the Riderski mine are smelted. Some river ports, as Khabarovsk, Blagoveshchensk, build and repair vessels.

Tanneries, tallow factories, brickworks and breweries are widely scattered. Only 7.6% of the pop. is estimated to be engaged in manufacturing industry (1914).

Communications.—Efforts to open up communication with Siberia by its northward flowing rivers and the Arctic Ocean have met with some success, but access by this route is possible only in the height of summer. Experience has shown that during Aug. and Sept. ice seldom presents any real difficulty in the Kara Sea and a steamer can rely on making the estuary of the Ob or Yenisei. One or two vessels take this route annually. Along the eastern part of the Arctic coast the only regular navigation is by occasional vessels between the mouth of the Kolima and Vladivostok.

The Ob affords 17,000 m. of navigable waterways, but the delta impedes communication with the Arctic Ocean. Seagoing vessels can reach Obdorsk, but large vessels have to lie at Nakhodka Bay in the Gulf of Ob. River steamers ascend the Ob to Biisk, 2,059 m. from the sea, and the Irtysh to Lake Zaisan, 3,100 m. from the sea. The Ob-Yenisei canal between the Ket and the Kas is accessible only to small barges. In 1913 there were 350 steamers and several hundred barges on the Ob and its tributaries. The Yenisei is navigated to Minusinsk, 2,045 m. from the mouth. Small seagoing vessels can reach Yeniseisk, but larger vessels discharge and load at Golchikha (Ghilghila) in the delta. The Yenisei is the only Siberian river for which sailing directions and large-scale charts are published. Beacons and buoys assist navigation. In 1913 there were 60 steamers on the Yenisei. The tributaries are of little value for navigation. The Lena has a navigable length of 2,760 m. to Kachugskoe, 230 m. from Irkutsk, the nearest point on the railway. In 1914 there were some 30 steamers on the river, mainly between Yakutsk and Vitimsk. The Vilyui, Aldan and Vitim are tributaries on which a few steamers ply. The Amur with the Shilka is navigable for 2,000 m. to Stryetensk on the Siberian railway. There are many sandbanks, but vessels drawing 3 ft. can make the whole journey. The river is buoyed and marked and supplied with a few dredgers. Seagoing vessels stop at Nikolaevsk in the delta, but if the stream was dredged in a few places they could reach Khabarovsk. In 1916 there were about 400 steamers and several thousand barges on the Amur and its navigable tributaries. Practically all the vessels were Russian, although Chinese vessels have equal rights down to Khabarovsk. On the Sungari, the Manchurian tributary of the Amur, there is Chinese and Japanese shipping. The Ussuri is navigable throughout its length. Steamers ascend the Ussuri and Sungacha to Kamen-Ribolov, on Lake Khanka, 500 m. from Khabarovsk. Navigation on Lake Baikal has become less important since the construction of the railway round the southern end. In addition to two powerful ice-breakers there are about 12 steamers on the lake, some of which ascend the Selenga. The shores of Lake Baikal are well provided with lighthouses. The best harbors are Baranchuk on the west and Misovski on the east. Both are provided with breakwaters and wharves and are on the Siberian railway.

In 1916 the railway mileage in Siberia was approximately 6,800 m., not counting the Chinese Eastern (trans-Manchurian) railway. The Amur railway was built between 1908 and 1916. It marks a reversion to the course originally projected for a railway to the Pacific and provides a through route independent of Chinese territory. The Amur railway is a single track linking Kuenga via the Amur valley with Khabarovsk, 1,295 m.; the embankments and bridge piers are built for a double track. There are branches to the Shilka river at Chasovaya, and to the Amur at Reinova, Chernyaeva, Blagoveshchensk, Innokentievskaya, and Pashkova. The bridge across the Amur at Khabarovsk is 7,038 ft. in length and has 22 spans. In western Siberia the line from Petrograd to Tyumen has been extended via Ishim to Omsk on the original Siberian line. A line from Ekaterinberg destined to reach Tobolsk goes via Irbit and ends at Saitkovo on the Tavla river. The Altai railway from Novo-Nikolaevsk to Barnaul (with a branch to Biisk) and Semipalatinsk, 408 m., was opened in 1915. It serves mining and agricultural interests in one of the most promising parts of western Siberia. The new line from Achinsk to Minusinsk, 300 m., opens a rich agricultural district in the valley of the upper Yenisei and tributaries. From Tatarskaya, 105 m. E. of Omsk, a line goes S. to Slavgorod, 196 m., in a region which in 1913 was attracting settlers. From Yurga, 385 m. W. of Krasnoyarsk, a line to Kolchugino, 200 m., taps rich coal-fields. These two lines were built by private enterprise. The Siberian railway is now double-tracked from Omsk to Karinskaya where the Stryetensk and Amur line begins. Some of the bridges still require to be widened. There is a double track from Nikolsk-Ussurisk, the junction of the Ussuri and Chinese Eastern railways, to Vladivostok. A line 93 m. long connects the Suchan coal-mines with Vladivostok. During the years 1915-6 the Siberian rolling-stock was much increased from the United States, and new railway shops were erected at Pervaya Ryeka near Vladivostok.

The telegraph system has been extended into Arctic Siberia: lines follow the Ob to Beresov, the Yenisei to Turukhansk and the Lena to Yakutsk and Vilyuisk. There are lines from Yakutsk to Okhotsk and from Khabarovsk to Nikolaevsk with connexion to Sakhalin. The Siberian telegraph system is linked via Semipalatinsk with that of Turkestan, and via Chuguchak with that of Mongolia. A second line to Mongolia between Kosh Agach, on the frontier, and Kobdo was incomplete in 1921. The Siberian and Chinese

systems join at Kyakhta. Wireless telegraph stations exist in many places in the far N., and in 1916 were working at Cape Mare Sale in the Yamal peninsula; Dickson I. at the Yenisei mouth; Novo-Mariinsk and Markovo on the Anadir; Gizhiga Bay; Okhotsk; Khabarovsk; Nikolaevsk; Petropavlovsk in Kamchatka; Iman on the Ussuri and Vladivostok.

SICKERT, WALTER RICHARD (1860-), British painter, was born at Munich, May 31 1860, the son of the painter, Oswald Adalbert Sickert, a well-known contributor to *Fliegende Blätter*, and grandson of Johannes Sickert of Altona, painter and lithographer. Walter Sickert studied painting and etching under Whistler in Tite Street, Chelsea, but in 1885, following the advice of Degas, began to paint from drawings instead of from nature. His first work on these lines, "Mammoth Comique," was published in the *Yellow Book*. The dramatic quality of his work owes much to his study of the technique of wood engraving and to his interest in the work of John Leech and Charles Keene, while he was also much influenced by Wilhelm Busch (see 4.869) and Adolf Oberländer (see 19.946). His subject pictures include "Mamma mia po' areta" (1903), "Noctes Ambrosianae" (1906), "The Camden Town Murder" (1906), "Army and Navy" (1913), "Ennui" (1914), "Sinn Fein" (1915), "Pierrots on Brighton Beach at Night" (1915), "Baccarat at Dieppe" (1920) and "Supper at the Casino" (1920). He also produced some architectural paintings, including "Hotel Royal, Dieppe" (1900), "Miracoli" (1903), "Lansdowne Crescent" (1917) and "Pulteney Bridge" (1918), while his best known landscapes are "The Happy Valley" (1919) and "The Priory of Auberville" (1919). Examples of his work are in the British Museum, Tate Gallery, Bibliothèque Nationale, the Luxemburg and the art galleries of Manchester and Johannesburg. He became a member of the Société du Salon d'Automne, the Society of Twelve and the International Society, and was a fellow of the Royal Society of Painters, Etchers and Engravers. As a teacher he exercised a strong influence over the younger school of British painters.

SICKLES, DANIEL EDGAR (1825-1914), American soldier and diplomatist (see 25.36), died in New York City, May 3 1914. In 1912 after having served for more than a quarter of a century as chairman of the New York Monuments Commission he was removed following the discovery of a shortage of \$27,000. His last years were disturbed by financial difficulties.

SIDGWICK, ARTHUR (1840-1920), English scholar (see 25.39), was in his later years an ardent advocate of the abolition of compulsory Greek at Oxford, both in the interest of the classics and with the view of extending the field whence the university should draw its students. He was also a warm supporter of the admission of women to the university degrees, as he

had previously been both of woman suffrage and indeed of all aspects of the higher education of women. He died at Oxford, Sept. 25 1920.

His elder brother, WILLIAM CARR SIDGWICK (1834-1919), also a classical scholar and fellow of Merton College, Oxford, died at Rugby, Oct. 18 1919.

SIDGWICK, ELEANOR MILDRED (1845-), British educationalist, was born in Scotland, March 11 1845, the daughter of James Balfour of Whittingehame and his wife Lady Blanche Cecil. She was thus the sister of Mr. Arthur James Balfour. She was educated at home, and in 1876 married the philosopher Henry Sidgwick (see 25.39). Mr. and Mrs. Sidgwick were both much interested in the advancement of the higher education of women, and were actively concerned in the founding (1880) of Newnham College, Cambridge, of which Miss Clough was the first principal. On the death of Miss Clough in 1892, Mrs. Sidgwick succeeded her as principal, and retained the position until 1910. In that year she retired, and until 1919 was bursar of the college. Mrs. Sidgwick shared her husband's interest in psychical phenomena, and in 1910 became secretary of the Society for Psychical Research.

SIEGECRAFT AND SIEGE WARFARE.—The earlier article on FORTIFICATION (10.679) reviews the prevailing ideas of defence against siege-warfare just before the World War. Opinion was then still unsettled on fundamental points, as well as on those differences in arrangement of the available elements of defence which have always divided the military engineering world into two or more schools. In the earlier days, Vauban and his competitors might disagree as to design, but they were in agreement as to purpose; and even at a later date, when the "bastion" school carried on its controversies with the "polygonal" or *caponnière* school, there was complete unity as to the necessity of permanent fortifications and substantial unity as to their functions. But the economic history of the 19th century, and the military history of its latter half, had brought the principles as well as the practice of fortification into the melting-pot.

Amongst many reasons for this, the following were the more important:—

(a) The increased size of armies, made possible by the credit system of finance, the universal service system of recruiting, the industrial system which could arm them, and the road and rail system which enabled them to disperse without risk in order to feed on the countryside, or to remain massed without starving through a breakdown of convoys, or both.

This increased size soon reached a point at which the old-fashioned fortress ceased to be an adequate base for the army's depots, or an adequate shelter in which to refit after defeat. There were signs of this even in 1870, although by that date the fortress had expanded into an entrenched camp of large perimeter, and between 1870 and 1914 the scale of field artillery, field transport and field ammunition for a given force, was practically doubled.

(b) The character of war, as between "armed nations," in which, in principle, a speedy decision by battle was sought at all costs, whereas warfare between the old professional armies had been prolonged from campaign to campaign. The objects sought by each side were now rather spiritual than material, or at any rate more general than local; and the fortress, which used to be judged according to the degree of protection it gave to the material objects of enemy desire—a city, a province, a port—came to be judged according to the degree in which it aided or impeded the manoeuvres of a field army seeking to win the war in battle. The task of fortification thus became much less positive and definite, and a programme of works took on a somewhat speculative character.

(c) Development of communications, which, besides the effects referred to under (a), had that of making civilized countries everywhere or nearly everywhere penetrable. The fortress as conceived of in the 18th and early 19th century, therefore, no longer exercised any power of control beyond the range of its guns or the striking radius of its semi-mobile garrison. And it could easily be "turned," and then either enveloped or—by

means of a masking force—eliminated as a factor in the campaign. Cases indeed remained, and still remain, of "obligatory points of passage," where local control of the route by means of fortification implies strategic control of the adjacent regions which are limited for their intercommunication to that route. Especially is this true still of rail communication. But in the main, armies and their transport can, in present-day west and central Europe, move where they will, except through areas directly under the tactical control of fortifications.

Further, the rapidity of communication as well as the wealth of routes enables a modern state to concentrate its defensive forces in the threatened region far more rapidly than of old, and the necessity for fixed defences, to gain time for the assembly of mobile forces, steadily declined.

(d) The development of the technique and manufacture of weapons of war, from about 1860, became so rapid that permanent fortifications of any given design were liable, like modern warships, to fall into obsolescence after a brief life of usefulness which contrasted sadly with the long career of a place like the old citadel of Antwerp, built in 1567 and besieged with all the forms and means of siegecraft in 1832.

Three out of four of these operating causes, it will be noted, are extrinsic, and one only intrinsic. In the case of the latter, operating alone, it is easy to conceive of a sort of duel between the gun constructor and the military engineer, analogous to the continued contest of gun *versus* armour plate. Few fortresses have ever had the good fortune to be fully up to date in design and equipment at the moment of siege. The reply of the French engineer who was asked what he would do if the Germans made the length of their scaling ladders greater than the depth of his ditches, expresses an inevitable condition of permanent fortification design. "It will always be easier," he said, "for the Germans to make scaling ladders than for me to dig ditches." Similarly, it will always be easier to make a new gun that will cut through a given thickness of concrete or armour than to increase the latter. For—questions of expense apart—the fort is a permanent sentry guarding against surprise, and the reconstruction of its works is a heavy piece of engineering which not only takes time but frequently renders them useless for the period of the repairs. Thus, in 1914, war surprised the fortress of Belfort when four of its principal works were under reconstruction. And if, as is generally the case, the programme of reconstruction is so drawn up as to minimize these risks, some part of the fortification system is sure to be obsolescent at any given moment. At any such moment, then, the question is not whether the means of attack have the upper hand—practically this is almost always the case—but whether the superiority is of such an order that the fortress or fort is useless. The new long-ranging powers of siege artillery in 1870, subjecting the area *intra muros* to concentric bombardment by an indefinitely numerous attacking artillery, and the demolishing powers of the superheavy siege howitzers evolved in Germany and Austria between 1900 and 1914—at least as against average concrete—were superiorities of that order.¹ But such cases are not frequent in military history, and it is more usual—in modern times, especially—to find a sort of thrust and parry, in which the artillery of the attack maintains a lead, but not a decisive lead.

The extrinsic causes in operation, meantime, were tending to bring about radical changes in the very meaning of fortification.

Outwardly, the controversies of the period 1885-1914 turned on technical questions, and chiefly on whether improvised fortifications could be shown to possess a resisting value practically equivalent to that of permanent fortifications. But in reality it was the feeling that the purposes and principles of fortification,

¹ Even in this instance, it must be admitted, the event was due in part to faulty designs which were not up to date even when laid down. Thus the new Antwerp forts (see ANTWERP) were only built to resist the 21-cm. mortar, although the Japanese had already, under very unfavourable conditions as to communications, managed to employ 28-cm. pieces at Port Arthur. On the other hand Fort Douaumont at Verdun, where the concrete was excellent (1892) and of adequate thickness, resisted a far heavier bombardment even by 42-cm. howitzers.

as they had been understood in the past, no longer responded to the needs of warfare, that produced the multiplicity of designs and proposals for artillery works and infantry works, armoured and unarmoured works, self-contained and mutually interdependent works, and so on, characteristic of the period of unsettlement. If most of this ingenuity remained, as it did, unconvincing, this was due to the fact that there were great general causes at work, of which, in default of war experience, only the existence and not the effects could be seen.

The size of armies steadily increased, all the European continental Powers being drawn into a competition based on the numbers of citizen soldiers who could be conscripted and financially maintained. The power of armament increased also, and with it the possibility of holding a wider front per unit of armed force. The special results of this, from the point of view of fortification and siegecraft, were the extension of perimeters and the thinness with which a circle or arc of investment could now be maintained. But the more general results were the more important. An army developed along a front of some hundreds of miles could no longer be worked by radial lines of communication centring upon one or two ring fortresses. In Napoleonic practice, a stronghold of some sort was always the centre of operations on which the army's movements pivoted; and only that portion of the theoretical base-line, which was in relation with the stronghold in use at the moment, formed what has been called the "effective" base. With the modern extended fronts, on the contrary, the effective base has widened more and more, until it practically coincides with the theoretical base. In other words, each part of a great army has its own lines of communication and its own sources, the connexion between the army line and the base line, or front edge of the home supply area, being a sheaf of more or less parallel routes. Whatever local variations may appear when portions of the system are isolated and examined by themselves, in the *ensemble* the strategic structure of warfare in civilized countries had become linear.

But the more the front extended, the more difficult it became to collect any considerable force at one part of it for offensive effort. The "parallel battle in all its horror"—unit facing unit all along the line—was admitted to be the negation of generalship. But whether the dispositions were made *a priori* or by manoeuvre within the battle, whether envelopment or breakthrough were the method chosen, the parallel battle could only be avoided by reducing the living forces on certain passive or semi-passive parts of the line to a minimum. The small economies that could be effected on these parts by judicious tactical arrangements in the open—though certainly not to be despised—would no longer suffice to give the really considerable superiority of force necessary for decisive victory on the active front. The expedient of economizing force by sacrificing territory had become, under modern conditions of social and economic life, more dangerous than it had ever been before. Recourse was had, therefore, to fortification. It became one of the rôles, if not indeed the principal rôle, of permanent fortification to economize active living forces on the passive fronts—a principle already applied to field fortification within the tactical sphere. As soon as the competition in numbers had set in all over military Europe, we find permanent fortification developing a new tendency to be *linear* instead of *circular* in type. The ring fortress becomes a sort of end-redoubt to a long line of forts, usually drawn along some natural barrier. This tendency is shown in the creation of the Meuse line (Verdun-Toul), and the Moselle line (Épinal-Belfort) in France, the line Namur-Huy-Liège in Belgium, the Sereth line in Rumania, the Bobr-Narw-Bug line in northern Poland, and lastly the Diedenhofen-Metz and Molsheim-Strassburg-Istein lines in Germany. In the same way, most of the new ring fortresses that were not so connected by permanent works were so placed as to be keystones of a linear battle-system; conspicuous instances are the systems Lille-La Fère-Laon-Reims-Verdun and Dijon-Langres-Épinal. Of the rest—setting aside the fortresses of eastern Europe where poverty of communications enabled permanent works, as of old, to dominate great areas by dominating a few nerve-centres—we

find Antwerp, Copenhagen, Bucharest, Paris, designed as self-sufficing ring-fortresses, but not so much for playing a part in a battle-system as for serving as refuge for an army and a government that for the time being could not maintain its line of battle in the open field. Three of these four were called upon in the World War to play the assigned rôle and it is significant that not one of them did so successfully. Bucharest was evacuated as the result of an unsuccessful linear battle in the foreground; Antwerp was given up by the Belgian field army and Government as soon as the choice had to be made between standing a siege and continuing the war in the open; while in the crisis before the Marne the evacuation even of Paris was seriously considered.¹ Two ring-fortresses, Maubeuge and Besançon, were constructed in France in advance of the battle-system, in order apparently to draw upon themselves a part of the invader's effort condensed on the wings, and to control certain nuclei of communications which might otherwise be useful to him as he pressed forward. But the latter task is really that of a barrier-fort, and indeed Maubeuge was in process of being converted into a pure barrier position when war broke out, the old intention of an isolated defence *à outrance* having been abandoned. The linear systems with end-redoubts, on the other hand, performed in the war all the services for which they had been designed, with the exception of Liège-Namur; and even in this case failure—so far as there was failure—was due not to any vice of principle but to other factors.

The tendency to force a speedy decision in battle at all costs, specially characteristic of citizen armies, could not but reinforce the effects that the size of armies in itself produced upon fortification. With such a tendency on both sides, the initial deployment on each side would inevitably be carried out, wholly or largely, in accordance with an *a priori* plan of battle. Strategic considerations for the side which had chosen the pure offensive and moral and political considerations for the side which had chosen the defensive-offensive, imposed concentration close up to the frontier, in the first case so as to seize the initiative, and in the second so as to surrender as little of the national territory and resources as possible. Frontier fortification therefore had as its first duty protection of a line or zone of railheads close behind it; and since railway communication is in principle highly sensitive, a system of ring-fortresses at intervals could not give the same protection against sudden raids as linear defences of equal trench-length. But there was a further consideration. An *a priori* scheme of battle, with frontage and not depth as its main characteristic, is liable to require considerable modification when contact has been made and the first serious combats have produced their varied results, and thus a regrouping process begins in the course of the operation itself. In this regrouping, fortification is called on not only to protect the lateral shifting of masses by rail (as for instance the moves of the French IX. and XVIII. Corps from eastern Lorraine to the Ardennes in the middle of Aug. 1914), but also to send away its own local reserves to the area of decision (as in the case of the three French divisions transferred from the Meuse-line front to the Somme at the end of Aug. 1914).

The more penetrable the country, the more pronounced the linear character of the fortifications that must cover it. Not knowing the direction of attack, the defender must either prepare for it at all points of his allotted frontage of influence, or else resign himself to giving up country that *ex hypothesi* is economically valuable, and manoeuvre in retreat to gain time. The old policy of devastating a deep zone to cover manoeuvre, occasionally practicable when the organization of the state was simple and predominantly agricultural, is almost or wholly inapplicable in an industrial country. In Oct.-Nov. 1914 Hindenburg devastated part of W. Poland as cover for a lateral regrouping. But when it came to including Upper Silesia in the devastation programme, industrial influences promptly intervened to mitigate it. The

¹ In the event Paris played the part, originally assigned to Laon-La Fère, of end-redoubt in the battle-system. Antwerp, after capture, was organised by the Germans for the same purpose, viz. to serve as end-redoubt to the Antwerp-Meuse line.

expedient of making even a narrow zone truly impenetrable by means of radical destructions, adopted by the Germans in France in the spring of 1917, requires both time and an elaborate labour programme, neither of which is available in a battle crisis. In some cases, inundations serve the purpose, but even inundations take time to spread. On the Yser front in Oct. 1914, five days elapsed between the order to open the sluices and the creation of an effective barrier thereby. Moreover, in a generally penetrable country the area of decision might turn out to lie in an unexpected direction, and, if so, a system of fortifications designed to protect regrouping by likely lateral routes might prove to be useless for covering those which actually were required to be used. Thus, a speculative element began to come into schemes of fortification. It was no longer possible to justify heavy capital expenditure on works by reference to plain and definite needs. Already it was admitted that if the unexpected happened, it would be necessary to make shift with improvised works; already a considerable body of opinion held that permanent works, if admitted at all, should be similar in general design to field works; and the tendency in these circumstances was inevitably to trust to the latter, which were cheaper, could be built just where they were wanted, and according to many experts were just as good in principle as permanent works, and indeed better than most of the expensive fortifications already in existence.

This underground growth of the linear principle was fostered by another cause. The time-honoured relation of the town and its defences was altered. Under the influence of tradition theory continued to conceive of the fortress as a circular defence round a town. But the town had ceased to interest the military engineer, who now called it the "nucleus." He disposed his ring of defences at such a distance as to protect the nucleus from bombardment, a convention which was imposing a larger and larger perimeter with every improvement in the range of guns, but his works were now meant primarily to take a share in the operations in the field. That being so, except in such cases as that of Port Arthur, where the nucleus contained establishments regarded as essential to the conduct of the war, it was almost a matter of indifference whether a particular town should be protected or not. The old relation of the town and its walls had been based on the fact that the walls preserved the town from pillage and murder. In the course of time this had changed to a great extent, and in the era of "cabinet wars" it had almost vanished. But the old mediaeval spirit of the towns came to life again in such instances as Zaragoza, Colberg, Venice, and even if the towns-people were indifferent or sullen, the governor could usually resist pressure from them, because he was strong in the conception of his plain duty as a soldier to defend the post entrusted to him. But when the defence perimeter had advanced out of sight of the town, and the *enceinte* had either been turned into a public garden or retained, demilitarized, as a historical monument only; when, further, in peace-time no military barrier whatever differentiated the defended area from the open country; when, lastly, two generations of railway traffic had destroyed the self-centred economic life of the town and blurred its particularism—then from the point of view of the town it was in much the same position as any undefended town or village in the theatre of war. It might come within the ambit of military operations or it might not; if it did, it might either resist the invader heroically in the manner of Belfort in 1870-1, or agitate for demilitarization as Lille did in 1914, but the fact that a ring of forts lay out in the country around it had very little influence either way on its conduct as a town. Open towns in modern times have behaved like fortresses of old, and fortresses like open towns of old.

Correspondingly, the position and outlook of the governor has changed. Formerly the town was his charge, and almost his viceroyalty. His troops were his own; organized for sedentary warfare and not for campaigning, they were not at the disposal of a field army which happened to be operating in the neighbourhood, and the town was in practice defended—sometimes with spirit, sometimes feebly—whatever course operations took outside. Up to the very eve of the World War a French fortress governor was responsible to the Government only, and took no

orders from the commander-in-chief of the field armies. The era of "cabinet wars" made little difference to this state of things; the population might be indifferent to the war in the towns as in the country, but to the governor and his troops the fortress was still a charge to be defended. Moreover, it was a real base for the armies in the field, in that the stores and supplies for those armies were accumulated in the fortress, and a real strategic aid in that it commanded routes that were obligatory for both sides. But when, in our own times, the governor had become simply the commander of a certain group of forces destined like other forces to take their part in a general scheme of battle; when the area within his defences had to a great extent ceased to be the source of stores and supplies for the field army, and when railways, needing protection at all points and not merely at a focus, became the principal lines of communication, the choice between evacuation and defence came to be governed by larger considerations of strategy. The governor's decisions therefore were assimilated in principle to those of any tactical executant of the strategist's instructions. He might defend or evacuate as a field commander might hold his ground or retire. But the peculiar character of his responsibility was gone. Even in France, the country which has been most tenacious of the fortress tradition, the old regulation, already quoted, was modified in the 1913 "Regulations for the conduct of Higher Formations," which empowered the commander-in-chief to assume control of any fortress and its forces if he thought fit.¹

On the German side, units made up from fortress garrisons formed quite one-third of the Eastern armies during the first campaigns of 1914 operating sometimes a hundred miles away from their fortress of origin and in the sequel, never returning to it.

In sum, therefore, causes of a general character operating before 1914 produced these tendencies: (a) to divorce fortifications from their nucleus or central town, (b) to make them rather linear than circular in trace, (c) to bring them into conformity with the battle-scheme of the field armies (with *déclassement* as the alternative), and (d) to construct them as far as possible according to the principles of field fortification.

The theory of fortification, on the other hand, was still bound by the notion of a nucleus, and unable, therefore, for the moment to employ its stock of ideas and methods to the best advantage. The practical technique of fortification and siegecraft was, meantime, progressing in details; reinforced concrete had come into normal use, armour was improving in quality, the defence had it in its power no less than the attack to profit by developments in the design of quick-firing guns and howitzers of medium calibres. Observation balloons and kites were available, superior to the old spherical types; wireless telegraphy removed some of the dangers of investment and made it possible to co-ordinate the activity of a besieged garrison with that of a relieving army. The technique of bored mines developed, and trench-mortars and grenades reappeared. The lessons of Port Arthur in matters of detail-tactics and design were assimilated in the various armies. The enormous defensive power of the machine-gun was realized and to some extent exploited. It remained to synthesize the application of these elements, old and new, in an art of fortification that responded to the new demands and conditions of warfare.

This art began to take shape with the introduction of the "group" principle. Advocated by several theoretical writers in the period of controversy, it was applied practically, and on a large scale, by the Germans in the celebrated *Feste* constructed on the Moselle and the Rhine in the last ten years before the

¹ It was in virtue of this new regulation that Gallieni's Paris forces were brought under Joffre's command in the battle of the Marne; and in accordance with the spirit of it that Sarrail acted in the same crisis, when, although only an army commander, he sent imperative orders to the governor of Verdun to despatch his mobile reserves to the battle-field of Revigny. The fact that the governor, General Coutanceau, though himself under attack, complied with this requisition instead of standing on his undoubted legal rights, is itself evidence of the changed outlook of the fortress governor in modern warfare. In a somewhat different way, the confused story of the *déclassement* of Lille in Aug. 1914 points the same moral.

World War. They may be considered from two points of view: locally, as examples of a type of fortification, and collectively as a defensive *ensemble*.

The *Feste*, as its name indicates, is rather a self-contained fortress on a smaller scale than a fort in the old sense. Although it forms with other such works, and with forts or batteries, part of a defensive system which as a whole may be either linear or circular, it contains within its own wire entanglements each of the elements of defence—artillery for counter-battery, artillery for flanking the intervals, and infantry works for the protection of this artillery against a close attack. But it combines them in a way which differentiates it in principle from the types of fortification characteristic of the 1873-1903 epoch.

In that period there were, broadly, two opposed schools of thought, and a school of compromise. One school, fairly perhaps designated as the French, favoured an arrangement in which the "forts" form the close-defence element and intermediate battery-positions the distant-defence element. The opposite, or Brialmont school, exemplified in the Liège and Namur works (see 10.698-9 for plans), relied on a simple ring of powerful self-contained forts, each including both these elements. Variations within the respective schools turned chiefly on the use or non-use of armour, some relying upon it for the protection of all defensive weapons, others confining it to the close-defence weapons and yet others excluding it altogether. The compromise school, favoured by Austrian opinion, sought to modify the characters of each type so as to combine them. In all cases, it should be added, the intervals were intended to be garnished in war with an improvised trench system, with its wire, its dugouts, and its machine-gun emplacements.

The *Feste*, on the contrary, attempts to combine the two elements of defence without modifying either. Full security for the long-range elements is given in principle by dispersing them, equally full security for the close-defence armament by concentration within an obstacle. To add positive or negative protection, armour is introduced wherever necessary, and loose and "provisional" as the forms may seem to the student of earlier fortification, it must not be forgotten that, structurally, every detail of the *Feste* is a piece of permanent work.

This very warning, however, suggests that it is necessary—more necessary than ever—for the student of fortification, whether practical or theoretical, to find a satisfactory answer to the question: What is it exactly that we require of "permanent" fortification in the tactical sphere?

The rôle of permanent fortification, it is suggested, is to give to the garrison or defence force a greater degree of security, and to its armament better conditions of employment, than "provisional," i.e. heavy field, fortification can give.

To prevent the enemy's guns from obliterating the defences of the front attacked, and thus enabling his infantry to make its way into the defended area, these guns must be counter-battered and (if possible) destroyed, but in any case neutralized as far as practicable. This implies a counter-battery armament on the side of the defence. According as the guns of this armament are exposed to enemy observation or not, they require, or they can dispense with, fighting protection. But in both cases, and especially in the second, they require to be screened against hostile raids or brusque infantry assaults that may develop during this counter-battery phase, emerging perhaps from dead ground close in front.

This protection can be given in the form of an obstacle to the enemy's passage, so serious that a great and organized effort is necessary to reduce it. Such an obstacle may be a deep ditch, or a system of wire entanglements or grilles, or both. Normally, the former is the better obstacle, but except in country already intersected with canals, wet ditches, river-channels, the use of a ditch requires that the armament to be protected shall be grouped very closely. Unless, therefore, the engineer and his Government are prepared to face the expense and provide cover of the solidest kind¹ the ditch as obstacle is usually excluded, so far as concerns

the protection of what may be called the main armament. The wire or grille, as compared with the ditch, is greatly inferior as an obstacle, but much more readily created, more easily destroyed, but more easily repaired also. Obstacles can be traversed, either after being broken down by bombardment in advance of the assault or by means of scaling ladders and bridges accompanying it. As against destruction by bombardment in advance, the only remedy of the defence is the counter-battery which entirely or partially stops the bombarding guns. But even without such destruction, the obstacle may be overcome by ladders and bridges, wire cutters, petards and other appropriate means, in the course of the assault itself, unless the work of placing these devices is made impossible by the defenders' fire. Hence the obstacle, whether it be ditch or wire, must be protected by a close-defence armament, and nowadays it is generally admitted that this armament must be a specialized organ. But how is this in its turn to be protected against destruction or neutralization at the critical moment? Practically by its own defensive arrangements alone. And thus, in the element designed to guard the obstacle, we reach the alternate unit of fortification upon which the whole system depends, that which in the last analysis ensures for the main armament the power of undisturbed counter-battery (in the case of a *fort d'arrêt* of keeping the forbidden area under steady fire).

The close-defence organ, then, has two functions—to protect other elements and to protect itself. The former presents no particular difficulty, and is merely a question of providing the necessary fire-power. But the latter is the critical problem of modern fortification.

If the counter-battery guns are concentrated, as in a fort, and the obstacle is a ditch, then—quite apart from the material cover required for these guns to enable them to fight—material cover is also needed for the close-defence organ, since its position is practically obligatory. But the cover is obtained relatively easily since the weapons covered are sunk to the level of the ditch-floor, and any necessary thickness of protection can be provided over it both on first construction and later.

But such a concentration of counter-battery methods creates large intervals between work and work, and access to the defended area (which with a dispersed main armament is automatically barred by the obstacles defending this and the fire of the organ which protects them) must be prevented by organs in the works so placed as to control the open zone. In some systems reliance has been placed on the counter-battery guns themselves to do this, but modern engineer opinion generally may be said to be opposed to this, since guns which have been engaged in the artillery duel may have been put out of action by the time that they are wanted for close-defence, and even if intact should be wholly absorbed in their proper task. The organ providing ditch defence, by reason of its situation is not as a rule able to undertake control of the open intervals; and in short the only alternatives are small cupolas or *traditore* batteries. The former are open to many objections. If built into the same work as the main armament they are almost as much exposed to premature destruction as the latter is² and must be provided with fighting protection on the same scale. If mobile, they are exceedingly costly in proportion to the fire-power they develop. For these reasons modern practice generally favours the *traditore* battery, which is a casemated emplacement (sometimes a cupola) at or near ground level, giving fire only to the flanks and rear of the work, situated in the rear portion of it and protected against bombardment to a great extent by the mass of the work itself.

But, from the nature of its duty, the site of the *traditore* battery is frequently obligatory, and when it is combined inside the same obstacle with a concentrated counter-battery armament, the needs of the latter as to site may conflict with those of the *traditore*. In the avoidance of this, perhaps more than in any other

¹ As Col. J. C. Matheson has pointed out, the closer the grouping the denser the material required to protect it.

² The cupolas of this class in the Antwerp forts suffered nearly as severely as those of the main armament, although they were hardly called upon to exercise their special functions, since the infantry attack of the Germans was not pressed into the intervals before the fire of the forts had been beaten down.

single factor, lies the central idea of group-fortification of the *Feste* type. Two dissimilar elements have to be both protected by the same obstacle and yet spaced some distance apart. But the obstacle (in such conditions mainly wire or grille) itself requires local close-defence. This "ultimate unit" has thus not yet been arrived at. Nevertheless, this ultimate unit, in group-fortification, has only to give short-range protection to the obstacle, and in practice it is an infantry-manned stronghold, designed to give fighting protection to its garrison,¹ sometimes provided for, its own local safety with a deep ditch and sunken flanking defences, sometimes organized with a fighting parapet frontally commanding an artificial foreground which is wired, but always having as its real function the protection of an obstacle external to itself.

In the case of concentrated main armament, therefore, it would seem that fighting protection for the counter-battery guns, for the *tradiore* batteries, and for sunk ditch defences is required to be designed on such a scale as will enable these elements to defy, actively or passively, the attack guns of the day and the morrow. The same applies to the shelters in which—in the case of group fortification—the garrison of the infantry work is placed in readiness to man the parapets, but not necessarily to these parapets themselves. Further, in proportion as wire replaces the deep ditch, as an obstacle, heavy and expensive work in peace-time is dispensed with.

In the system of deployed main armament, on the other hand, the proportion of permanent work, it would seem, can safely be much less. With modern artillery means, the sites for counter-battery armament are rarely obligatory; observation must be provided for; but the actual position of the guns, and therefore the line of liaison between observation post and guns, are—to a great extent at least—free from limitations of ground. This being so, the close-defence element of the fortifications may be disposed to the best advantage for carrying out its task—that of protecting a system of obstacles suitably placed between the battery zone and the enemy.

In point of permanent work, then, although parts of the battery positions themselves may occasionally require concrete or even armour, concealment of virgin earth, and alternative positions in the great majority of cases afford all necessary protection. For the close-defence guns, on the other hand—the element which must be able to endure at all costs—the chosen positions are often (if not in most cases) obligatory, and full-scale fighting protection must be given. Even so, there being by hypothesis no necessity to develop frontal fire, and the volume of the required lateral protective fire being relatively little, a permanent work which is essentially a *tradiore* battery and nothing else can be both small and well-covered against frontal fire at an expense much less than that of a great self-contained fort. Its own local protection may be either a ditch with sunk defences or an infantry system surrounded by wire, but these auxiliaries, too, would be withdrawn from the crest facing the enemy to positions on the reverse slope. The only case in which it would be necessary for any part of the system to go forward to the crest and front slope would be that in which the artillery observation and command post is combined with the *tradiore* in one work or one enclosed group. In such a case the post in question would undoubtedly require special treatment as regards its own close-defence. But all that in principle is necessary is that the post and its liaisons should be immune.

On the other hand, the security of the main armament against a rush of hostile infantry was far greater when an obstacle defended by fire completely surrounded it, and military engineers were very loth to impair this security. No doubt, when the obstacle covering the front of the batteries in the deployed order was fully organized, the latter might be considered safe enough for practical purposes so long as the interval-defence remained effectively in action to protect it. But a danger period was foreseen in which the obstacle was not yet fit to perform its function with certainty. The "brusque" or (more accurately) the "abbreviated

¹ The term "storm-proof," frequently applied to such infantry works, hardly seems to connote their real function.

attack," proposed by the Bavarian General von Sauer, had many supporters; and as the tendency already mentioned, of modern warfare between "armed nations" is to push the line of resistance as nearly up to the frontier as possible, the fortifications of that line were in fact exposed to instant attack.² Those of Verdun and Toul were little more than 20 m., the easternmost fort of Liège only 13 m., from the German frontier, while the western Metz forts could be bombarded from French soil. In former days, this would have mattered less, but the growing mobility of heavy artillery—from about 1800—for the first time made it possible to employ true siege artillery within a few hours of the opening of hostilities. The attacker, on the other hand, naturally had to forego some of the power of his attacking means in attempting a *coup*. His truly mobile siege artillery was limited, or supposed to be limited, to the calibre of 21 cm. Heavier pieces though they no longer took weeks or months to arrive in their emplacements, at any rate took days to do so, and by a sort of general agreement (to which however there were exceptions) the situation was met by placing a part of the main armament of the defence—called the safety armament—inside a closed obstacle. Usually it was an existing fort that was adapted to house the safety armament, but sometimes it was included in the design of a new work. The fort thus in practice reverted partially to its old duty of serving as a battery position, while in theory its function had become entirely that of locally protecting a *tradiore* or other interval defence. The distinction between property and accident was no doubt clear to specialists, but the result was that the generality of armies and peoples continued to look upon a fort as their fathers had looked upon it, till the astonishing events of Aug., Sept. and Oct. 1914 so thoroughly undeceived them—too thoroughly, indeed, for in the revulsion, not merely safety-armament guns but even interval-flanking guns were removed from closed works.

In the system of group-fortification, it was naturally much easier to house a safety armament. No element within the ring of wire need cramp any other, or be drawn into the fighting activity of another, or suffer from the shells intended for another.³ Full fighting protection will be necessary, as is always the case with safety armaments, but, as has been noted above, with more room the same safety can be given with less expense.

In sum, therefore, the necessity of compromise on this question of safety armament has caused the dispersed-elements and the concentrated-elements schools to agree upon: (a) the group or *Feste* principle for interval-flanking elements, obstacles and defence of the same, and safety portion of main armament; (b) the order principle of deployed artillery, with an obstacle covered by flanking fire, for the remainder of the main armament. This, it will be noted, leaves a real liberty for the treatment of particular cases. The proportion of total armament installed as "safety" is whatever the designer chooses to make it in each instance, the *Feste* being adaptable to any proportioning within reasonable limits fixed by the contour of the ground. A practical check on enclosing an unnecessarily high proportion will always be the expense of giving full fighting protection.

Examples of Group-Fortification.—Types of forts, both main armament forts and others, being described and illustrated in to.696,

² To wire a perimeter or frontage of 30 km. to a depth of eight yd. only requires three eight-hour shifts of (in round numbers) 6,000 workers each, as well as mechanical, animal or human transport for about 4,000,000 yd. of barbed wire, weighing 300 tons or so, and 100,000–130,000 stout posts. Other work to be done includes the clearance of the field of fire, the digging of trenches, the construction of shelters (if not in existence already), opening of communications and liaisons, etc. Land which is occupied by a fortress garrison in war rarely belongs to the Government in peace.

³ This can be demonstrated by the "theory of probabilities." Assume a main-armament cupola 16 ft. in diameter, under accurate attack by a gun having a probable error of 60 ft. in range and 3 ft. in line. Calculation shows that this will probably be hit by 7% of the shots fired. Now assume a *tradiore* element having a vulnerable surface on top of 20 ft. from front to rear and 25 ft. laterally. Placed with its front edge 120 ft. behind the centre of the cupola, this will receive 3.62% of the shots aimed at the latter. Placed with the front edge 240 ft. behind, it will be hit by 0.2% of the shots. In other words, at twice the distance it is eighteen times as safe.

it is only necessary here to consider examples of the newer group-fortification. Three forms may be taken, one of which, the Metz form, has been applied on a large scale, while the others, though academic examples, are fully representative of principle.

Common to all, it will be seen, are: (a) a wire obstacle round the whole group, and behind it an infantry trench-position; (b) very large area, equalling that of town and fortifications together in some of the old Vauban fortresses, and six to eight times that of the typical 1873-1903 fort; (c) batteries, closed and under armour, for the guns of the main armament (or safety armament) irregularly disposed within the wired area.

So far, all are in agreement. But beyond, there are some important differences. Thus, the Metz group, and those proposed by de Mondesir, both possess powerful infantry works with ditches, whereas the Austrian type lacks this element. Again, de Mondesir and the Austrian text-books agree in attaching the greatest importance to the *traditore* element, remarkably neglected in the Metz works—at least as originally built. Lastly, the Austrian and German engineers tend to place the centre of gravity of the artillery, and even that of the infantry, defence well forward, while the French author puts them as far back as possible, with only observatories and frontal trenches in the forefront of the area.

The Austrian design (fig. 1) as the simplest, is taken first. On the height 130 is an armoured battery P B, containing four 6-in. howitzers in cupolas, with an observation post in a small cupola in the centre.¹ Between the cupolas are magazines for the storage of 800 rounds per gun. A passage runs along the backs of the cupolas and ammunition rooms, and two barrack rooms are provided at the ends, with other small rooms as offices, etc., in the centre. In the actual design the thickness of the concrete is, in places, less than 2 metres, which is considerably below present-day standards.

On the forward slopes at S, S, S, are small works, combining in each 2 cupolas for quick-firing guns (intended for frontal close-defence, not main-armament work), with an armoured observation post between them and a shelter for infantry and machine-guns in waiting, to man the trench-line against assault. These are built with a roof of about the same thickness as that of the main-armament battery. On the rear slopes are two powerful *traditore* batter-

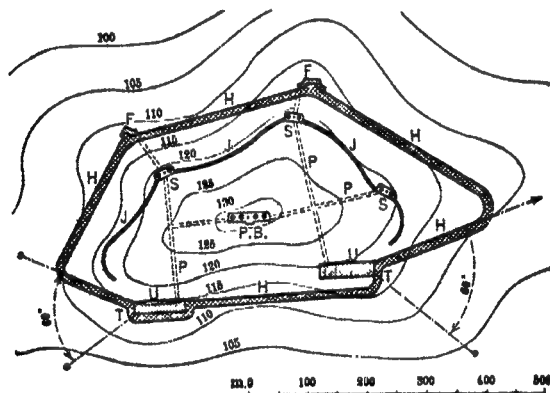

FIG 1.—Austrian Type

ies, T T with quick-firing guns (4 to 6 in each, in order to have sufficient for a distributed fire over the interval, in case fog or darkness makes accurate aim impossible). The inner parts of the concrete masses are organized as barracks (U) and magazines. The *traditore* is in two tiers, the upper commanding the country outside and the lower sweeping the (wired) bottom of the ditch. Armour is used for the faces of the gun casemates and nearly 3 metres of concrete form the roof. Those parts of the wired ditch not swept by the *traditores* are flanked by counterscarp casemates (F F) containing machine-guns or pom-poms and protected by 2.8 metres of concrete. Tunnels connect the various elements of the group. In this design, which is simple and, owing to the absence of refinements that would not stand bombardment, strong, there are nevertheless some points of weakness, which may be discussed here, not by way of criticism but because they afford convenient illustrations of certain practical points which the engineer cannot ignore.

The whole of the front work depends for its intimate flanking upon the counterscarp casemates, F F. In such cases it is necessary to protect the backs of the casemates and their communicating galleries from mine attack, by providing the roots of a counter-mine system at the outset. This was a form of attack which played a considerable rôle at Port Arthur. It is perhaps the only way of

¹ This is a miniature of the gun cupola, with a telescope placed in the port. The development of the periscope now makes the provision of protected command ports much easier than it was at the time of this design.

dealing with counterscarp casemates, but it is an effective one. At Fort Vaux (Verdun) the Germans made their way through a counterscarp casemate into the tunnel system of the fort, and the terrible gallery fighting of Port Arthur repeated itself. But, unlike the Japanese, the Germans had no difficulty in gaining access to the galleries in the first instance, as the French had themselves blown away the backs of the casemates in order to get convenient access to some external trenches. It is noteworthy that in the final stages of re-fortifying Metz on the group principle, the Germans were careful to provide the foundations of counter-mine systems. In the Austrian design here considered, nothing prevents the development of mine attack on these casemates except the fire of the central battery P B and the batteries, S, S, S, all of which are exposed and liable to neutralization or destruction by counter-battery. The depth of the ditch containing the main wire varies, and no walls exist to make it an important obstacle in itself. The integrity of the obstacle therefore depends purely on the fire of the counterscarp casemates, and—quite apart from the question of mining attack on these—later war experience has shown that there is great risk of the flanking fire being impeded or intercepted by the debris produced by intensive bombardment. This weakness is common to all ditches, and the problem of keeping the field of fire open had not yet been solved in 1921. But it is evident that the longer the ditch, the more chance there is of a heap of debris collecting at some point in it. In any case, it would seem that to attempt ditch protection for the whole perimeter of a group work involves the expenditure of money that might more profitably be devoted to other elements of defence. Another defect seems to be the small number of the infantry shelters, having regard to the time required for the defending infantry to come out and man the parapet. This is the more important, as this design altogether lacks the strong self-contained infantry work which is the kernel of those now to be described. The evolution of Metz as a ring-fortress is dealt with at 10-696. Allusion is there made to new works in progress outside the existing perimeter. These were the famous *Feste*. They were built in succession from 1899 to the outbreak of the World War, and were continued and practically completed in 1915. Their characteristics were only approximately known at that time, but when Metz was retroceded to France by the Treaty of Versailles, not only their present condition, but their history and cost accounts became available. (See the French official *Revue du Génie* of Jan.-Feb. 1921.)

The *Feste* in fig. 2 (from the *Revue du Génie*) shows an actual example. It should be understood that the Germans designed the earlier works of this class with a minimum of defensive precautions, notably in respect of external interval flanking, but that, in the later works constructed in the two or three years prior to the World War, there was a marked tendency to develop the hitherto inadequate external flanking, even at the expense of the main armament, which on this line of evolution would, in due course, have become a "safety" armament only. The group-work illustrated is rather of the earlier than of the later kind, as it is lacking in the *traditore* element. But it is one of the greatest advantages of the group-work over the cramped fort that additions and alterations can be made as required, and in fact many such works at Metz were provided later with 57-mm. and 77-mm. *traditore* batteries.

The *Feste* forms an irregular quadrilateral, measuring, from outer edge to outer edge of wire, 1,200 yd. from front to rear and the same from flank to flank, with an area within the outermost wire of about 120 acres. At the front and rear angles there are strong and minutely organized infantry works, which form the basic units of the system: their rôle is to flank the wired perimeter and to look after their own close-defence as well. At the right and left angles, the perimeter trench takes the form of redoubts, which contain, in their forward sides, infantry observation posts, and, in their rear sides, both observation posts and organs for flanking the rearward wire. In the interior of the *Feste*, four armoured batteries for main armament are disposed irregularly and each has a war barracks attached, communicating with it by underground passages. The perimeter trench is provided at intervals with armoured sentry posts. The artillery observatories are aligned on the front slope, and have tunnel connections with their batteries. The fifth battery is a dummy—a device freely used in these Metz works, in which there is plenty of room. The perimeter wire is sunk to a depth of 2 metres, and the ground in which it is bedded is sloped up to the infantry line, which has the lowest command compatible with its functions. This perimeter wire is carried round the main works (01, 02) also (though partly unflanked), but the strength of these lies in their inner system. Behind the perimeter wire and the advanced parapet or covered way lies a deep ditch (20 ft.), wired at the bottom and provided with a concrete counterscarp. The floor of this ditch is flanked (in the case of the forward work 01) by a double counterscarp casemate at the apex and a small *caponnière* in the gorge.

About the same time as these Metz works were being evolved in Germany, Lt.-Col. (afterwards General) Piarron de Mondesir, in France, advocated another type of group-fortification, which, though generally of the same class as the *Feste*, shows some characteristic differences.

De Mondesir's group is in general outline oval, or rather lens-shaped, with the curved front towards the enemy and the flattened front towards the defended region. Like the *Feste* it bestrikes the

natural crest. Immediately beside the main wire is a continuous infantry parapet, which has at frequent intervals concrete shelters for machine-guns as well as infantry. On the natural crest, a central structure of concrete and armour contains the commanding officer's observation post and two machine-guns in cupolas for the direct

FIG. 2.—Plan of a Metz Feste. References. sweeping of the foreground, and towards the flanks two somewhat similar structures house each a 75-mm. Q.F. gun, its observation post, and the observation post of one of the main armament batteries mentioned below. Just behind the crest are two large battle-

batteries," was destined to survive and multiply in the World War. The rear defence of the inner system is provided by the rear portion of the perimeter trench, with its concrete machine-gun shelters and its wire.

The most marked characteristic of this design is the fact that the interior space of the "group" is organized principally for step-by-step close-defence, whereas it is utilized in a *Feste* for battery sites. The middle foreground is under the fire of two quick-firing guns in cupolas, but the author of the system evidently does not trust to these organs overmuch, for he arranges that they shall be fired into and destroyed by the main-armament guns if captured. The essential element of the first stage of close-defence is the machine-gun detachments in the front trench, which are housed under concrete till the moment of action. The second stage, which begins when the assault has broken into the front trench, is a combination of counter-attack from the great shelters behind the crest with machine-gun fire from the central crest cupolas; to facilitate this counter-attack, the back of the front trench is smoothed to glacis-form. When all this is lost, the inner system with its "infantry batteries" sited well down the reverse slope, has still to be carried before the main-armament or *traditore* batteries can be reached, and the machine-gun cupolas of the keep not only coöperate in this third stage, but (with the blockhouses attended to earlier) make it difficult for the enemy to make a lodgment even in the fourth and last stage. In all stages after the first, the curved fire of the trench-mortar battery plays a part. In this respect, and in the free use of machine-guns and local counter-attack, de Mondesir's fortification anticipated by ten years or more the trench-warfare methods that developed in the World War.

The above outline account of applications, practical and theoretical, of the new "group" principle requires the addition of a few details as to the principal constituent elements of such works,—the counterscarp casemate or *caponnière* for low-flanking of a ditch, the main-armament or safety-armament battery made up of cupolas (as distinct from the cupolas themselves), and the *traditore* battery.

The Austrian counterscarp casemate, illustrated in fig. 4, is constructionally a simple example. Under the counterscarp wall, on the further side of the ditch, facing the salient angle of the work, a chamber is formed with embrasures for rifle, machine-gun or light-artillery fire along the two adjacent ditch lengths. In this case armour is used for the embrasures, each gun-room (K K) having two very light guns or pom-poms. B is a living room for the squads assigned to the defence, A a latrine, St a stairway leading to P, a concrete tunnel under the ditch which communicates with the body of the work.

Fig. 5 shows a counterscarp casemate of more advanced type. It is amongst the most modern examples of such structures, forming part of a 1914 work at Metz. It fires in one direction only. The inner portion of its mass is in ordinary, the outer in reinforced concrete, and the total thickness is 3 metres. Fire is arranged in two tiers, for rifles, and for machine-guns, and one embrasure (the safest) is allotted to a searchlight. The details are worthy of close attention. The top of the wall is formed as an overhang, under which the fronts of the fighting chambers are recessed. This gives enhanced protection from fire, and also from the risk of grenades

FIG. 3.—Section of infantry work O 1 of fig. 2, on line a-b.

shelters in concrete for counter-attack infantry. Then, well back, comes an inner system forming a still flatter "lens." This contains the main armament batteries, the *traditore* element, and the infantry keep. Its front wire traverses the whole interior of the group, leaving the crest elements and counter-attack shelters outside it, and resting its flanks on the infantry parapet, the junction being sealed by blockhouses. Within this wire, which is protected frontally by several "infantry batteries," i.e. loopholed steel screens or pent-houses for riflemen, lie, towards the flanks, two batteries of main armament artillery in cupolas and one or two "Bourges casemates"—genuine *traditore* batteries which can only fire to the flank and rear and are heavily protected and masked towards the front. Centrally placed between the artillery positions is the infantry keep, in this case as in the German the basis unit. It is four-sided and has a deep wired ditch which is flanked not by counterscarp casemates, but by two low *caponnières* springing from the base of the escarp at the diagonal angles. In the concrete of this keep are the war barracks of the whole garrison, observation cupolas, and at least two machine-gun cupolas which are in fact the essential defence of the keep. Embryonic counter-mine systems are provided at the salients of the keep. Behind the keep is a battery for small short-range mortars—a novelty which, unlike the present writer's "infantry

being thrown in by an assailant overhead. At the foot of the wall is a pit which lowers the floor of the ditch so far that the assailant in the ditch cannot reach the embrasure. This pit also serves to take debris that might otherwise mask the fire of the lower tier. A gallery formed in the mass of the counterscarp connects the casemates of the different angles.

An example of the modern counterscarp is shown in fig. 6 from another Metz work. Here it will be noticed that, for defence and also for ventilation, the gallery possesses a loophole. Over this is a grille to prevent the placing of scaling-ladders and the upper part of the counterscarp wall is formed to a peculiar section which gives a minimum foothold to an assailant scrambling down, and presents an unfavourable striking angle to all projectiles.

The Mass—for it is a mass rather than a wall—is 7 metres thick for 7 metres of height. The communication tunnel between such a gallery and the body of the work (fig. 7) gives 2 metres of (ordinary and reinforced) concrete protection besides that afforded by the earth of the ditch floor.

Some designers, owing to the risk of the backs of counterscarp chambers and galleries being breached by mining, or the communicating tunnel destroyed from above or below, prefer to keep the ditch between the enemy and the flanking organ. In this case a

low caponnière is built out into the ditch from the escarp or from the mass of the work; in the work of fig. 2 the ends of the two-story concrete barrack are arranged to act as caponnières.

Fig. 4

An unusual flanking organ designed for Metz is shown in fig. 8. Here the difficulty of giving sufficiently thick protection for an organ flanking wire at or near ground level (e.g. the outer wire of a *Peste*) is met by providing a

Fig. 5.—Counterescarp Casemates.

a rule dispersed over the open ground comprised in the "group" they require subterranean communications with each other and with their observation posts. The latter are sometimes included in the same concrete mass with the gun cupolas, but it is more usual to withdraw the battery mass behind the crest and to push the observatory forward. Batteries are often wired in, and sometimes given means of local protection against surprise attack. They contain not only a large stock of ammunition, but also, nowadays, laboratories and workshops.

Fig. 6.—Counterescarp from Metz.

Traditore batteries, by hypothesis, fire only to the flank and rear. They are thus always placed, so to say, behind a corner; that is, protection is accumulated in front of the gun casemates, and this protection is continued laterally for such a distance that a projectile from any likely direction will either meet the covering mass or pass clear of the gun muzzles. The original form is that designed in France and known as the "Bourges casemate" (fig. 9) from de Mondesir's *Fortification Cuirassée*.

Fig. 7.—Communication Tunnel to Counterescarp.

A larger *traditore* of Austrian design is shown in fig. 10. This is formed in the end of a concrete mass of which the remainder contains the war barracks, storehouses, etc. The lower embrasures flank the floor of the fort ditch, the upper—the real *traditore* battery—sweep the flanks and rear of the external intervals. (T T are the gun casemates; B St is the post of the officer controlling the fire; M M the ammunition room; G S a small flanking element to control the ditch just under the *traditore*.) Armour is used to reduce the thickness of concrete, both vertically and horizontally.

The gun usually employed in *traditore* batteries is a field gun of about 75-mm., or a gun of the small naval or tank class, 57-mm., being the commonest calibre. Pompoms (1-pdr. Maxims) and even machine-guns are also found, but as a rule it is the field artillery type of effect that is required and provided for. Cupolas are sometimes, but rarely, employed, as their characteristic virtue of all-round fire is not wanted.

Administrative Arrangements.—Any work that has to act in isolation, or semi-isolation, is provided with all the necessary "services." Store-rooms, hospitals, barrack-rooms, etc., with all

furniture and equipment, must be formed in the interior of the available concrete masses; water must be laid on, lighting and heating provided for. Though hitherto it has not been thought desirable to provide power for working cupolas, etc., it has already become necessary to include a power-room (dynamos and Diesel engines) in the equipment of the *Feste*.

FIG. 8.—Flanking Organ (Metz).

Amongst these auxiliary arrangements, there is one, however, which during the World War proved to be of predominant importance—ventilation. The fall of the forts of Liège and Antwerp was largely due to the ventilation arrangements proving inadequate. Poisonous fumes from the burst shell penetrated the concrete fissured by its explosion, and filled the underground galleries of the fort, asphyxiating or disabling a large proportion of the already overstrained garrison. In the latter part of the war, the development of gas warfare added a further complication, as it became unsafe to draw in air from outside. The solution adopted by the French for the Verdun forts (which, it should be noted, no longer contained either main-armament or *traditore* artillery, but had become pure close-defence infantry works) was to deliver filtered air from a considerable distance, under slight pressure, to certain rooms in the fort, which were sealed against local air by air-tight doors or otherwise. All men working elsewhere than in these rooms wore gas-masks. Although the group principle of fortification, by dispersing the elements of defence, *ipso facto* dispenses with the subterranean labyrinths of the Belgian forts, and so reduces the effects of explosion fumes, the fact remains that the men in the armoured batteries and the *traditore* and flanking organs, must be protected from gas entering

either by embrasures, cupolas, scutings or fissures, while pure air must be supplied and foul air evacuated somehow. It may be, indeed, that the question of aération, hitherto subsidiary, will become one directly affecting the fighting design.

Materials.—Earth was always the common property of permanent and of field fortification. Before 1914 concrete and armour were reserved for permanent work, but during the World War both came into use for heavy field works as well. Further, as both in permanent and field work care is taken nowadays to disturb the natural earth as little as possible, and tunnelling freely employed, relief being kept down to a minimum, there remain only, as specially characteristic of permanent work, (a) the heavily armoured, deeply-sunk, mechanically highly finished gun-mounting, and (b) the great concrete mass. It is not unreasonable to consider the necessity, or otherwise, of these elements in a fortification scheme as a criterion of the necessity of "permanent fortification," using the words here in the technical sense for fortification of a kind that can only be carried out at leisure in peace conditions.

face. Monlamville received 330 hits by 42-cm. shell. The more exposed forts, such as Douaumont and Souville, deluged with medium and field as well as heavy shell, received over 30,000 hits apiece. Thus, cupolas of the thickness and quality of those of Verdun are capable of all necessary resistance.

FIG. 10.—Austrian Traditore.

Even more marked is the discrepancy between the behaviour of concrete at Liège and Antwerp and its behaviour at Verdun; as in the case of armoured gun mountings, the Belgian sieges brought concrete into discredit. Here, however, it is a question of quality of material and of conscientious painstaking work. The best concrete has a resistance such that a test bar will break across the stones rather than the cement; the worst is feebler than virgin earth, especially rooty earth. The Verdun concrete had not only been well made, but had also been given an adequate safety margin of thickness; and it was found that, in spite of the volcanic bombardment, 3 metres of special concrete or 2 metres of reinforced concrete, or 2½ metres of special concrete (or 1.75 metres reinforced) disposed as an apron overlying an old masonry vault, with a sand cushion interposed, would steadily resist calibres up to 42-cm. inclusive. Although the effects of these monster mine-shell were felt in the ground to a depth of 14 metres (nearly 47 feet), the fissuring which had ruined the Belgian forts does not seem to have occurred at Verdun.

In the Metz *Feste* the characteristic disposition is a mass of ordinary concrete with a thick outer casing of ferro-concrete. An arrangement which is favoured by some engineers is to dispose reinforced concrete in layers separated by air-spaces; this had not in 1921 been subjected to the test of siege. The lesson of Verdun, however, is held to be not so much that it proved 3 metres to be a sufficient thickness, but that it demonstrated the importance of *mass* as a material element of resistance and *depth* as a *moral* element. The smaller concrete masses suffered under bombardment much more severely in proportion than the larger, and it is considered therefore that organs small in themselves such as *caponnières* should form part of a larger body of concrete, as in fig. 2, or, or in fig. 10. As regards depth, it was found that in tunnelled habitations well below the level of the forts—the foundations of which at Verdun are in rock—*moral* remained unimpaired by the heaviest bombardment. At Antwerp, from the nature of its site, no such burrowing was practicable, and the *moral* of the defenders was subjected to a fresh strain at the explosion of every monster shell.

In sum, armour and concrete in masses calculated according to the lower standards of a previous epoch, but given a safety

margin in application, proved capable of meeting the heaviest strain of bombardment which history records. The problem of the engineer to-day is to determine what safety margin is required for new work or reconstruction calculated according to the standards of Verdun.

A fixed resistance, *in situ*, of several months, then, is practicable with the materials and means of permanent fortification. That it is not so with those of field fortification is shown by the various trench-warfare offensives of 1916-7. At Verdun the German attack progressed rapidly till it confronted a close-defence system which had permanent works as its backbone. At the Somme, though the Allies' progress was slow, it was sure, and the defense finally evolved a system of "elastic" or "collapsing" resistance, which by its very nature implied the giving-up of ground until an organized counter-attack could be mounted for its recapture. The success of this type of defence, so long as the *moral* of the defending troops, and their skill in group, platoon and company tactics, remain high, is a matter of history. But it is equally a matter of history that there are positions which, strategically or morally, must be defended to the end without yielding ground, on which the defender must say, with Pétain at Verdun, "*On ne passera pas.*" And it is for these cases, so far as they can be foreseen in peace, that permanent fortification exists.

The very words of Pétain's defiance, however, carry the implication of a linear system. Fournier at Maubeuge, Kusmanek of Przemyśl—governors of ring-fortresses—could not say that the enemy "shall not pass," for the enemy could go round. It was not Verdun the ring-fortress, but Verdun the end-redoubt of the fortified line Verdun-Toul, that compelled the Germans to traverse Belgium in August 1914. In 1916 Falkenhayn hesitated between Belfort and Verdun as the objectives for his attack. Both had been ring-fortresses, but both were now key-points in a long line of battle, and derived their whole strategic importance from that fact. At Liège, we find the ring-fortress splitting itself into two halves which acted to the best of their ability as successive barrier positions. At Antwerp the attacks on the defence were purely frontal; and indeed, save Przemyśl, not one ring-fortress attacked in the World War was vigorously invested and attacked by convergent radial efforts. But it is perhaps Metz which affords the clearest illustration of the modern tendency to convert the stronghold into the barrier. From 1899 onward the old ring becomes of less and less importance, and the *Feste* were not only disposed on a wider perimeter, but collectively took the form of a sort of a parabola instead of that of a circle or ellipse. Facing westward, the system began with a group of *Feste*, forming an end-redoubt; and at the same time the pivot of the field armies that were to swing through Belgium, at Diedenhofen (Thionville), then ran southward along the Moselle to the neighbourhood of Metz, where it curved westward, passed round the S. of the old ring, and E. of the Moselle, took a new direction north-eastward, till finally it was completed by the "Nied position" (created on mobilization) which connected it to the stable line of battle that would be formed by the middle Saar. The southern bend of the system is about 14 m., the westward-facing limb 36 m. and the south-eastward-facing limb about 38 m. in frontage, the whole differing in scale rather than in principle from the familiar "Western Front" of the trench-warfare years which constituted between the Oise and the Moselle a great salient with the apex at Verdun. Outside this blunted redan, Diedenhofen-Metz-Rehlingen, the Germans were prepared to yield ground, but on it the defence was meant to be absolutely stable. The growth of the linear tendency is discernible even in the creation of the successive parts of the system. Beginning with the endeavours to increase the perimeter of Metz itself, the Germans presently bore away at a tangent on each side of the southern sector. The individual *Feste* became longer in proportion to depth, and finally, in the case of the Amanvillers-Horiont works, of 1912, attained a frontage of nearly 2 m. and consisted substantially of a great ditch with its flanking-organs.

Correspondingly, a change follows in ideas as to interval organization. It is evident that, in a ring-fortress of the 1873-1903 type, the individual "forts" occupy only a small proportion

of the perimeter as compared with group-works. The latter, therefore, allow of an extended perimeter for the same admissible intervals. Presently, as we have seen in the case of Metz, the perimeter attains an enormous length, and the ring opens out on the home side, becoming a gigantic redan or salient which comprises a whole region. The standard interval between work and work continues to be honoured at and near the exposed apex, but the gap increases towards the rear till near the root of the salient permanent work may give place to field work and simple utilization of natural obstacles, as in the "Nied position."

In the early 19th century, the ring-fortress was practically an enlarged enceinte-fortress with the curtains omitted. Later, though perimeters increased (in order to prevent bombardment of the "nucleus"), the forts still contain the whole of the main armament and retain responsibility for the defence of the interval against methodical attack. The interval is organized according to the needs of minor tactics, so as to prevent the enemy penetrating to the nucleus by any method but regular, large-scale attack. At the next stage (which is the most important in the evolution of ideas) the main artillery (except the safety-armament) is taken out of the forts and deployed in the intervals, the forts becoming "strong points" on a line of battle which has to protect this artillery. It is this stage which is represented in fig. 11, taken indirectly from a semi-official Russian work of 1913, by Colonels Golyenkin and Yakovlev (which, incidentally, marks the acceptance in Russia, after long opposition, of the principle of armour protection).

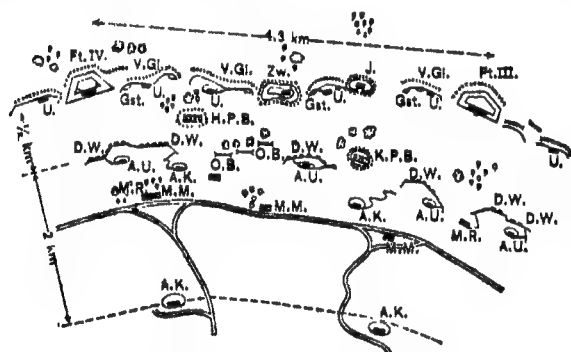

FIG. 11.—Russian Fort, close-defence.

The "fort" is a large and elaborate close-defence work designed specially for the sweeping of the intervals by *traditore* batteries, immunity of these being secured by a full equipment of flanked ditches, quick-firing guns under armour and fighting shelters. The arc of fire of the *traditores* is sometimes carried unusually far forward, as it is laid down in principle that special flanking guns, in or out of the fort, must cover the ground from 1,200 yards in front to 700 yards behind the next fort. No part of the main-armament is included in the fort.

From fort to fort, the interval, it is laid down, should not exceed about 4,500 yards. Otherwise, the responsibility placed on the *traditores* is too heavy (the average interval of Verdun, it may be remarked, is only about half this), and closed infantry work (Zw. in the plan) may sometimes be required to command some part of the interval that is not well covered by the forts. Frontally, the interval is held by a number of separate trench-positions formed with glacis foregrounds (V. Gl.) and provided with concrete fighting shelters (U.) and sometimes barracks (J.). Some of these positions have their own light quick-firing guns (Gst.) for flank protection. Four to five hundred yards in rear of this guarded obstacle are armoured batteries (H.P.B., K.P.B.), wired in, which contain the "safety" part of the main-armament with its ammunition. For the rest of the main-armament, battery positions (D.W.) with (M.R.) shelters for detachments on duty (A.U.) and protected barracks for those in waiting (A.K.) are prepared 600–800 yd. behind the front line and connected up as required by trenches. For other batteries, told

off as a mobile reserve, positions are marked out (O.B.). The main magazines of the sector are shown at M.M. and barracks for the third relief of artillery at A.K. in rear.

Apart from the batteries of the safety-armament and occasional foreground-flanking guns not comprised in the forts, peace-time work on the intervals is limited in this example to the construction of fighting shelters, barracks, magazines and the walls of battery positions. But, as soon as permanent work of any sort appears in the intervals, these begin to lose their blankness, and it is a short step to the modern conception of position-warfare—the attack and defence of a long, shallow zone which contains in its forefront the close-defence and in its rear portion the distant-defence elements. In this zone, permanent work will, we may predict, be called upon to perform the services which field and heavy field work cannot perform. It will provide, generally, those of the essentials which cannot be improvised (such as the concreted or armoured infantry, machine-gun and flanking-gun positions, required in the more exposed sites), and in key sections, those which will make the local defence as nearly as possible inexpugnable. And since, as explained earlier, these key sections can be in many or most cases predetermined, whereas the exact position of the rest may vary according to the opponent's plan of campaign, the greater part, if not the whole, of the material protection obtainable with a given expense will tend to be concentrated in them. Thus they may continue to be labelled with the names of towns or other localities as of old. But, essentially, they will be planned in relation to things outside and not to things inside, themselves. They will secure, or deny to the enemy, the use of certain ground or certain communications, definitely and completely. Locally, in order that the close-defence component may fully secure the operation of the distant-defence component, the permanently fortified key section may form a ring, or possess turned-back flanks of considerable length. But in the ensemble, and in many cases even locally, the tendency will be to reduce the depth and increase the frontage of permanent fortifications, so that the works of standard strength which can be built with the available funds may offer the widest direct and positive barrier to an enemy.

New Weapons in Siegescraft.—The evolution, during the World War, of weapons essentially unlike those for which the permanent fortification above-outlined was designed to use and to meet, raises the question—what modifications, if any, do these new weapons impose?

If the conclusion reached above be correct—that permanent fortification has now become, from general causes, the backbone of position-warfare, instead of being a thing apart—it follows that the new weapons will affect it in any case through their influence on position-warfare generally. Were it the case, for instance, that aerial warfare totally superseded land warfare, the ring-fortress might return in a new form as the means of protection of flying bases. But such speculations would serve no useful purpose here, and it is preferable to confine ourselves to the modifications of detail to be expected in permanent fortification as such.

Chemical Warfare is a term covering several very different weapons. Smoke which "blankets" the defence organization, gas which disables the defenders, vapour-producers which infect areas, are all tactically dissimilar. The strength of chemical warfare as against fixed defences lies in their fixity, its weakness in the fact that anti-gas protection is not limited, as it is in field warfare, to apparatus and devices that can stand rough usage and be carried without inconvenience by the already burdened soldier. One form of anti-gas defence has been mentioned above—the supply of pure air under slight pressure to rooms sealed from contact with local air. Improvements on this line of progress would include more and more of the interior chambers of a work in the protected space, while other devices made the gun embrasures as gas-tight as possible. The most important defence against gas is the impermeability of the structure of the work itself, which practically means its solidity under bombardment. The direct influence of aircraft on permanent fortification is not easy to estimate. There is no limit to the power and flexibility of anti-aircraft guns sited in fixed defences. All fighting elements in the works are fully protected against the attack of super-heavy artillery, and *a fortiori* against that of air-bombs. The attack of *traditore* or *caponnière* embrasures by machine-gun fire from low-flying planes, if practicable, could be

easily countered. Direct attack from the air, therefore, is not likely to affect design seriously. But observation from the air is another matter. Local superiority in the air may pass, in the course of the operations, back and forth several times, and design has to provide against the unfavourable case. It may be assumed with certainty that, in prolonged operations (such as by hypothesis the reduction of a permanently fortified front would entail) every battery position of the defence would be photographed, whether inside a group or fort or placed in the "interval." The defence is thereby compelled either to change position very frequently, or to build in. In the latter case, either the guns must have full fighting protection, or must be so buried and camouflaged as to be practically invisible to eye and to camera at a height of, say 15,000 ft., even when in action, while at the same time provision must be made for confusing the enemy's sound-ranging records. Here, then, the engineer is in the hands of the artillery researcher. Should the latter not succeed in producing gun-mountings, ammunition, and sound-camouflage (so to call it), which can defy the air-observer and the sound-ranging instrument, the engineer will be compelled to put his main armament again under concrete and armour, and perhaps to concentrate it somewhat. The alternative of frequent changes of position has many disadvantages, chief of which perhaps is the probability of having to traverse areas systematically infected by mustard gas.

Armoured Vehicles in the World War were of two classes, the slow-moving cross-country tank and the armoured car. It seems probable that these will fuse into one class, the fast tank. The tank was originally designed for traversing and crushing wire entanglements, and it is in this capacity that permanent fortification is chiefly concerned with it, for the defenders of solid permanent works are practically immune from its actual attack. The question for the engineer is—will the present types of obstacle-flanking organ succeed in dealing with the tank, and if not, how must they be modified? One type of obstacle, the deep ditch with vertical counter-scarp, is impossible for the unprepared tank, but such ditches are liable to be bridged at ground level by suitable girders carried by a "bridging" tank; and the best safeguard of permanent works against invasion by tanks is the fact that the latter must traverse a belt of ground which is swept at close range by an organ specialized for that duty alone, and invulnerable to the tank's guns. Although the dimensions of tanks will doubtless be taken into account in planning ditches, the first care of the designer will be to provide flanking pieces sufficiently powerful to destroy the tank as it crosses the line of fire, and to provide flanking fire in such a form that a disabled tank will not mask it. More generally, permanent works which form a section of a long battle zone will be organized to participate in the anti-tank defence of the system, and for this duty the *traverse* batteries are naturally the most appropriate organ.

The armoured car, or fast light tank, owing to its ability to make an inroad from a great distance at the shortest notice, may prove very dangerous to a fortified area which is in the crisis of mobilization and war armament. Special measures to deal with this risk could never be omitted; so far as fortification is concerned it would seem necessary to maintain at all times a clear field of fire for, and a state of readiness in, the *traverse* batteries, as well as in such gun positions of the safety armament as command obligatory or probable points of passage in the foreground.

Field and Heavy Field Fortification.—The methods of field fortification in vogue at the outbreak of the World War (see 10,719) were concerned essentially with light fortification, that is, incidental fortification on the battlefield. Starting from the conception of an advance brought to a standstill or a retreating army turning to fight, the engineer gave the infantry man types of works which were defensible after an hour's labour and which could be improved gradually during a more prolonged stay in the position. Lateral and overhead cover were provided, but only against rifle, machine-gun and the lightest artillery fire. Great stress was laid upon concealment, obtained by moulding the work as closely as possible to the ground, turning exposed soil, keeping relief as low as conditions of effect allowed, and also upon communications; a system of short trench lengths was preferred to long continuous lines, which entailed unnecessary labour and assisted the enemy to locate the defences. A good field of fire up to 400 yd. from the rifles was considered essential. Pivotal positions, whether localities, woods or hills, were organized for all-round defence. These principles, so long as the general course of the operations retained the foreseen open-warfare character, substantially justified themselves; perhaps, indeed, they justified themselves only too well, since it was the great strength of even lightly fortified fronts which compelled each side, in France, to extend ever further and further to a flank in the hope of turning the opponent's frontal defence, and so in the end produced a trench-line that was continuous from the Swiss frontier to the English Channel. The deadlock which ensued marked the beginning of a position-warfare which was locally indistinguishable from siege warfare as that term was understood in 1914. Nor was it only from the point of view of local, minor tactics that the analogy of siege operations held good. The succeeding campaigns were indeed a siege of the east front of Germany, whose western offensives of 1916-8 have sometimes been described by the Germans themselves as *sorties* from the *Festung Frankreich*. For the Allies, as against these

offensives, the nature of the defence, especially after the middle of 1916, resembled that of an investing cordon attacked by a desperate *sortie*, and fighting to gain time for the arrival of forces from other parts to drive in the prisoners and bolt the door again,—though it is true that the siege was mutual and the "sortie" was at the same time a penetrating assault.

Regarded from this point of view, the principal factors which, directly or indirectly, governed revolution were: (a) a theatre of war richly provided with communications; (b) highly developed industrial resources at the back of both sides; (c) enormous numbers of men and therefore labour power; (d) an initial situation of tactical deadlock in positions not deliberately selected but representing only the line on which offensive effort in open warfare had expired; (e) the haunting idea of a break-through, followed by exploitation in open-warfare in the old style.

Taking the technical effects of (d) and (e) together, it was inevitable that positions naturally unsound should be maintained by an equilibrium of forces acting in opposite directions. The attacker of the moment was necessarily attracted by these weak sectors, while the side which intended to attack in the future had a strong motive for holding as forward a position as possible. Fortification was called upon to make these intrinsically unsound positions safe, and all its resources in design and labour were taxed to the utmost to meet the call.

Taking (a), (b) and (c) together, we find these factors enabling each side to produce, to bring up and to apply *in situ*, technical stores on a scale hitherto undreamed of in siege warfare.

Taking the factors singly (a), by enabling artillery to be collected in enormous strength for an attack, compelled field fortification to develop unimagined powers of passive resistance, and by facilitating the concentration of great attack masses, induced commanders to strip non-offensive sectors of every human defender who could be spared, thereby forcing fortification to adopt forms which required a minimum garrison. By (b) there were brought into current field use not only materials hitherto reserved for permanent work, e.g. concrete, but also novel scientific devices and weapons of war, such as the air camera, gas, tanks, and, above all, improved methods of production, which increased the quantities of guns, ammunition and machine-guns available per unit of living force. By (c) trenches and obstacle-lines were multiplied to such an extent that there were eventually 20 to 25 miles of trench-work for every linear mile of frontage. Through (d), in the first year of trench-warfare, numerous bitter fights were engaged in on all parts of the battle-front for minor rectifications of position; in these fights there were developed new forms of detail tactics, with corresponding demands upon rear resources for a varied armament for the front-line combatant, whose equipment finally comprised, besides rifle and bayonet, grenades (hand and rifle), the light and medium trench mortars, flame throwers, periscopic sniper-rifles, knives, clubs, helmets and body-armour, not to mention gas masks. It led, further, to the retention of waterlogged trenches, and so to the introduction of pumping apparatus, trench-flooring, and other bulky non-combatant stores, into the front line. Through (e) it was demanded of fortification that it should protect both the masses of men assembled for attack and exposed to enemy "counter-preparation," and also the minimized garrisons of other parts of the front. These factors, operating, singly or together, with different relative intensity at different times, caused position-warfare to evolve, between 1914 and 1918, through three distinct phases, which may be distinguished by the titles field-fortification, position-fortification, and zone-fortification. The first of these characterized the western front from the end of the battle of the Marne to about the end of 1915, and the eastern front from the beginning of stabilization (which occurred at different periods on different parts of the front) to July 1915, and then again from Oct. 25 1915 to the end of the war on that front. On the eastern, Salonika, and extra-European fronts, evolution did not pass beyond this stage, because in these theatres the more important of the factors above enumerated were more or less inoperative. The second stage, position-fortification, is that of the Battles of Verdun, the Somme and the Aisne and the Artois battles of 1917; also of Asiago and the last six of the Isonzo battles on the Italian front. The third stage, zone-fortification, is characteristic of the Flanders battles of the latter half of 1917 and of all the 1918 battles. These indications of date do not of course imply that the changes specified came into force, formally and simultaneously, at any specific time. They are landmarks in the evolutionary process, which in this, as in other things, does not tolerate leaps.

In the first period fortification devotes itself, substantially, to the improvement and multiplication of the trenches bequeathed by the expiring offensives of 1914. The trenches are deepened, kept narrow, provided with more numerous traverses and shelters, though the protection afforded by the last-named only with difficulty manages to keep up with the increasing volume of fire from the enemy's medium howitzers. The close ranges at which the 1914 offensives died out have left the opposed front lines separated by a very narrow "no man's land," which is heavily wired by both parties. Concealment, as understood before the war, has thus lost its significance, more especially as all trench systems are regularly photographed from the air. Detail fighting produces the need of circulation and supervision trenches and other parallels behind

"the trench," and calls for more numerous communication-trenches, to which there is no further objection on the score either of concealment or economy of labour. In plan, the general result is an irregular skein of trenches, from 50 to 150 yards across, following the contour of the front line, which itself undulates considerably and at certain points forms sharp cusps or salients of local importance. The closing-in of key positions for all-round defence, which figures in pre-war fortification, has become more thorough, and internal subdivision has converted these wired-in areas into the "Labyrinth" of Neuville-St. Vaast, the "Hohenzollern Redoubt" of Hulluch and the "Tropée" of the Champagne battlefield. At the same time the interpretation of what constitutes a "key" position is different; it is chosen in relation to the trench system rather than in relation to the ground. Mining plays no small part in the fight for the possession of particular hillocks, or trench lengths, with a view to improved observation or better defence. But from the standpoint of evolution, the most important difference between 1915 and 1918 work is the deliberate withdrawal of the infantry firing-line behind the military crest of the position. This was far from being universal in practice, but it had become the recognized ideal. As in permanent fortification, so also in field, the preservation of the close-defence element from bombardment was the motive of abandoning the command of the foreground. Stress begins to be laid, especially, on the local flanking of wire by machine-guns in covered emplacements. But—again as in permanent fortification—the needs of the artillery observer frequently conflict with those of the close-defence; and each local problem, solved according to the value attached to these conflicting requirements at one time, has to be re-solved by fighting when the conditions change.

In this phase there are no marked innovations in the materials employed. The works are cut deeply in the earth and revetted by the conventional sandbags, hurdling, etc. of the text-books; details typical of trench-warfare fighting, such as trench blocks, sap-heads, island traverses, have been added. The "shelter" has become the "dugout," roofed in by layers of logs, house material, or in exceptional cases railway iron, and as a rule, though not always, withdrawn from the front line into one of the parallels behind. Guns are casemated, and dugouts provided for their ammunition and personnel as well as for a variety of command posts, aid posts, signal offices and the like.

In the second phase, which grew by degrees out of the first, the technique of fortification is modified owing to new conceptions of general tactics and to the bringing in of different materials. This is the phase that will remain forever typical of the western front campaigns. Its chief tactical characteristic is intense preparation and concentration of means of all sorts on the attack front, with a corresponding absence of the surprise element. The first consequences for fortification were: (a) the deepening of forward dugouts, and their construction by mining methods which leave the natural earth undisturbed; (b) the quasi-certainty of losing the first trench system, at least temporarily, with the certainty of its being reduced to a tormented ruin in any case; (c) reliance for close-defence upon the concealed machine-gun almost to the exclusion of other weapons; (d) multiplication of systems instead of multiplication of trenches in a system; (e) more elaborate provision for the maintenance of supply for forward troops, represented in practice by the accumulation of stores in forward dumps of all sorts. It was in positions organized on these lines that the Germans fought out the battle of the Somme. But their Higher Command did not at first accept the implications of (b), and paid a heavy penalty for attempting the impossible task of holding the devastated front line in strength. Especially heavy was their loss in prisoners, due to the "deep" dugout, which was so deep that the men could not get out of it in time to man the trenches. Yet without adequate protection it was impossible to hold the front line, or any other line, under bombardment, even after converting it into a line of machine-gun posts; and the first modification due to the Somme experience was the introduction of the only alternative to the deep dugout, viz. concrete. This was a step of great importance, both tactically and technically. Concrete had already been used, here and there, to reinforce parts of an earth-system, and was constantly employed in various back-area installations. But it was not till the latter part of 1916 that it became the principal material of "field" fortification. Instructions for mixing quick-setting concrete, and even for making ferro-concrete, on the spot begin to figure in training manuals, and in the chief belligerent countries a new industry springs up for the manufacture of standard concrete elements, which are transported to the scene of operations and built up as required. The timber, mine-gallery framing hitherto used in dugouts gives place largely to standard semi-cylinders of corrugated iron, also made at home and transported to the front in great numbers. Thus the ideal dugout for troops becomes a concrete structure lined with corrugated iron, proof against all field and medium calibre without being buried to any great depth; and the machine-gun emplacement and its dugout are fused in one concrete or ferro-concrete structure of the casemate type, famous in 1917 under the name of "pillbox" or "Mebù" (in full *Maschinengewehr-Eisenbeton Unterstand*). With this, the trench itself becomes of secondary importance. Though tradition and its undoubted usefulness in all circumstances except those of great-battle days made

the command in all countries exceedingly unwilling to give up the trench altogether, it is the chain of dugouts and machine-gun casemates, which, with the wire, defines the "position" of position-warfare at its highest development in the spring of 1917.

In the broadest sense, a "position" consists of several distinct, and more or less parallel, systems, each of which is at such a distance from the one in front that the enemy's artillery must change position—with all the attendant difficulties and delays of repairing communications through the battle-devastated area—and mount a new attack. At intervals, a switch-line, designed on the same general principles as the parallel lines, is drawn so as to bolt off the area which may be lost in one battle phase. Between the first and second systems lies a zone in which a very active infantry resistance is carried on by means of "strong points," which are no longer labyrinths of the 1915 type but well protected and wired-in machine-gun strongholds, resembling in principle the *tranchées* batteries of permanent fortification. With these as a basis, light trench-work will be run out in the directions required by the battle-situation from time to time, e.g. so as to fence off a lost sector; and for this purpose conveniently situated shell-holes are made defensible so as to constitute the framework of such lines. Tunnelling is largely used for short communications, especially where forward slopes have to be held so as to include artillery observation positions. The trench system bequeathed by the older methods is now broad (12 ft.) as well as deep, and is utilized as a covered-way, defensible in emergencies, rather than as a battle element. From 3-ft. to 5-ft. thickness of concrete (or ferro-concrete) over corrugated iron covers the casemated guns and machine-guns. With dugouts of similar design (the old deep dugouts are now sealed up or filled up by order of the command) these constitute the new defence system, whether disposed in lines or belts along the frontal systems or switch-lines, or scattered in the intermediate areas. Wire is now disposed in very wide belts, and does not conform to the direction of the trenches but lies in irregular salients and reentrants, each part under the eye of some machine-gun or trench-gun casemate. In short, the site of the "position" is governed by the needs of artillery observation, and by those of supply, while the organization of the site is based on the time, labour and material available for the construction of casemates and dugouts of concrete.

But "trench" warfare has thereby divorced itself from the element which has been its characteristic for ages, the trench, and from June 1917 to the close of the World War is the period of zone-fortification. The elements of defence are now dispersed in innumerable "nests," containing machine-guns, anti-tank guns, or counter-attack groups. The "position" attains hitherto unheard-of depth, and its forefront is held only by outposts, whose function is to police the ground in quiet times and give warning of assault in battle. Behind the "outpost zone" lies the "battle zone," in which machine-gun and anti-tank-gun defence break up the attack, which a counter-stroke then sweeps back to its starting points. As a precaution, a "rear zone" is organized behind the battle-zone. But field-fortification has at this stage been completely merged in field tactics, which it assists, no longer by ingenious tracing of lines of defence, clearances of foreground, economical disposition of working parties and materials, but simply by placing, at points indicated by the tactician, standard casemates and personal shelters, borrowed from the practice and made with the materials of permanent fortification.

Thus, while permanent fortification is concentrating its stock of ideas and devices upon the task of holding a long front of diminished depth, without any yielding of ground whatever, against the heaviest bombardments, field tactics have become fluid and mobile, ground being lost and won almost as readily as in the days of "manœuvre" warfare, though by different methods. It is at the points of junction between permanent fronts and field fronts; where particular features of ground are neither quite indispensable nor yet of negligible importance, that a field-fortification of the future will presumably find its proper scope. Like the zone-fortification of 1917-8, but to a further extent, it will have at its disposal many of the forms and methods of permanent fortification. SIENKIEWICZ, HENRYK (1846-1916), Polish novelist (see 25.54), died at Vevey, Switzerland, Nov. 14 1916.

SIERRA LEONE (see 25.54).—There was a modification of the S.E. frontier in 1911, when Sierra Leone acquired the Kanre-Lahun district from Liberia in exchange for a district on the Morro river. The new boundary was delimited in 1913-4, Col. Cowie being the chief British commissioner. The total area of the colony and protectorate is estimated at 31,000 sq. miles. The census of 1911, partly based on estimates, gave a population of 1,402,878, Freetown, capital and chief port, having 34,090 inhabitants. The European population numbered about 1,000, that of the colony (as distinct from the protectorate) being 702, including 62 women; the Sierra Leonians some 70,000. There were also some hundred Syrians, almost all traders.

The commerce of Sierra Leone is bound up with the products of the oil palm, which constitute some 75% of the exports. Next in importance is the kola nut, in universal demand among the natives of West Africa; scarcely any of the nuts reach Europe. Minor exports are ginger, piassava fibre, gum copal, rice and hides. Rubber and ivory have virtually ceased to be exported; cotton-growing experiments were abandoned. Native cocoa plantations have been made since 1910 in the Northern Shebro district, but up to 1920 cocoa did not figure in the exports. From 1909 to 1913 (inclusive) there was a steady expansion of trade, the total value rising from £1,960,000 to £3,481,000, imports and exports being almost equally balanced. Revenue showed a corresponding expansion, from £361,000 in 1909 to £618,000 in 1913. Expenditure in the years named was £336,000 and £622,010 respectively. During this period, in 1912, an extension of the railway going north from Boia junction on the Freetown-Liberian border was begun. In 1916 this northern line reached Kamabai, 118 m. from Boia and 182 from Freetown. A loan of £1,000,000 raised in 1913-4 was expended as to £308,000 on railway extension and as to £110,000 on improvements to Freetown harbour. As to shipping, British tonnage in 1913 was 2,050,000 out of a total of 2,931,000 tons, and during and after the World War the proportion of British tonnage increased.

At the beginning of 1914 a fall in the prices paid in Europe for palm kernels, rubber and other products of the country led to a decline of trade, and the outbreak of war in August aggravated conditions, as the German market was closed. Some 87% of the palm kernels had been exported to Hamburg, and the British kernel-crushing machines could not cope with the great quantity of kernels diverted to the Liverpool market. The erection of new oil mills in England—the oil enters largely into the composition of margarine—met this difficulty, but in 1915 a decrease in the market value of the kernels led to a smaller return from a larger output than in 1914. By 1917 however the quantity of kernels shipped exceeded that ever previously exported and also realized a higher price. Of 58,000 tons exported France took 1,380; the rest went to the United Kingdom. Thus the readjustment of trade was safely accomplished. As to palm oil, next to kernels the most important export, the greater part was always taken by Britain. (Of 828,750 gal. exported in 1919—the largest quantity exported for 10 years—Great Britain took 819,375 gallons.)

By 1918 the total value of trade was £3,197,000, the United Kingdom taking over 50% of the exports and furnishing over 80% of the imports, the United States providing the bulk of the other imports. Trade in 1918 surpassed in value that of any year since 1913, and there was a further marked rise in 1919, when exports were valued at £2,101,000 and imports at £2,034,000. Excluding Government imports, exports showed an excess over imports of £12,000, as compared with an excess of imports in 1918 to the value of £163,000. The high figures both for 1918 and 1919 were, however, due largely to inflated prices, though there was also an increase in the quantity of exports. Revenue in 1919 was the highest recorded—£748,000, expenditure being £740,000. The estimate for 1921 put both revenue and expenditure at over £1,000,000.

The colony and protectorate made progress in spite of the World War. There was an increased demand for education among the natives, chiefly met by the missionary societies, but the Government maintained schools for Moslems, and an agricultural training college for vernacular teachers was established at Njala, in the protectorate. In 1919 there were 163 elementary and intermediate schools in the colony and protectorate, with an average attendance of 6,285. Including secondary and technical schools there were in all 192 centres of education with over 12,000 pupils on the rolls. Sir L. Probyn, appointed Governor in 1910, was succeeded (1914) by Sir E. M. Merewether, and (1916) by Mr. R. J. Wilkinson. The natives showed much loyalty to Great Britain during the World War, and the Sierra Leone forces played a prominent part in the Cameroon campaign.

Notwithstanding the increase in trade, 1919 witnessed much distress in the colony and protectorate. Owing to adverse weather conditions in 1918 and an epidemic of influenza at harvest time, there was a great shortage of rice and other food crops, and famine resulted. This led in July 1919 to serious rioting, the Syrian traders, who were accused of hoarding food-stuffs, being attacked and driven from their houses and stores. As the bulk of the kola nut trade was in the hands of the Syrians that industry suffered severely. The high price of imported goods also caused much distress. The year was further notable for the prohibition of the import of "trade spirits," but it was not until 1920 that total prohibition was enforced.

SIFTON, SIR CLIFFORD (1867-), Canadian politician, of Irish descent, was born in Middlesex, Ont., May 10 1867. His father, John W. Sifton, was Speaker of the Manitoba Assembly, and the son, after graduating at Victoria University, Cobourg, was called to the Manitoba bar in 1889, and six years later entered the Manitoba Legislature as member for North Brandon. He was Attorney-General and Minister of Education in 1891, became K.C. in 1905, and joined Sir Wilfrid Laurier's Dominion Cabinet in 1896 as Minister of the Interior. He represented Canada at the International Conference on Conservation of Resources at Washington (1909) and was chairman of the Commission for Conserving the National Resources of Canada (1909-18). From 1910-7 he was Premier of Alberta and president of its Executive Council. In 1917 he became Minister of Customs and Inland Revenue in the Dominion Cabinet, exchanging that portfolio for the Ministry of Public Works in 1919 and becoming Secretary of State for Canada. In that capacity he represented Canada at the Peace Conference in Paris and signed the Treaty of Versailles. He was created K.C.M.G. in 1914 and was sworn of the Privy Council.

SIGHTS (see 25.60).—Although in the years before and during the World War, the instruments employed in artillery work were considerably improved and developed, research was in the main directed rather to auxiliary instruments such as range-finders than to gun and rifle and machine-gun sights as such. It may be said, therefore, that the modern artillery sight, as designed before 1914, stood the test of war; and the task of the present article is only to review developments. In one respect, however, those developments were wholly new. The anti-aircraft sight which was virtually non-existent in 1910, has already become an elaborate instrument and its evolution is still in progress. Considerable importance—practical rather than technical—attaches also to the new machine-gun panorama sight and to the application of aperture sights to the military rifle and light machine-gun.

Gun Sights.—The purpose of a sight is to ensure the accurate laying of the gun both in direction and elevation. The sight must provide for movement in a vertical plane to register the "angle of sight," the "tangent angle," and hence the "quadrant angle," and thus the range for which the gun is laid; also for movement in a horizontal plane, to allow the direction of the gun to be corrected for deviation due to "drift," wind, want of level and any movement of the target. In order that the operation of laying shall be unaffected by firing, the sights are in modern equipments fixed to a non-recoiling part of the carriage; this may be the cradle, the trunnions, or the intermediate carriage, and, in the last-named case, it must be so connected to the trunnion that the same angular movement is given to it as is given to the gun.

Laying for elevation may be accomplished in the following ways:— (a) By setting the required tangent angle in the sight and directing the sight-line upon the target. (b) With fixed mountings on level platforms, the quadrant angle may be registered on an elevation or range indicator incorporated in the elevating system; or, with both field carriage and fixed mountings, the gun may be laid at the required quadrant angle by means of a clinometer. (c) With fixed mountings at a definite height above sea-level, by connecting the sight through a cam with the intermediate carriage in such a manner that for a given quadrant angle the sight is automatically depressed to the correct angle of sight.

Laying for direction may be either direct or indirect; direct when the sight-line is aligned on the target, indirect when a convenient object or auxiliary aiming-mark is used. It may be accomplished as follows:— (a) By aligning the sight-line upon the target, the inevitable deviation of the shell from the vertical plane containing the gun being allowed for automatically, or set on the sight as deflection. (b) By using a panoramic sight and any convenient aiming-point; the horizontal angle between aiming-point and target is determined and set on the sight and the latter aligned on the aiming-point. (c) With fixed mountings, by obtaining the direction from an independent source and setting it on the oriented training-arc on the pedestal.

For laying both in elevation and direction it is essential that the sight should be truly vertical. This is attainable easily with a fixed mounting; but with field carriages the wheels or the platform may be out of level; in such a case, the elevation registered on the sight will not be correct, and the gun will shoot towards the lower side. If, however, the verticality of the pivot be maintained, it is immaterial whether the carriage basic structure be level or not. Adjustment for verticality is permitted by the reciprocating principle, in which the sight can always be made to move in a vertical plane parallel to that containing the axis of the gun. Thus the sight-line

and gun, when laid, lie in parallel vertical planes, so that neglecting drift, etc., correct direction is obtained.

Means to compensate automatically for drift of the projectile by giving appropriate deflection to the gun are usually introduced into the sight. As drift increases with the range, so also does the necessary deflection; but in some instances, a fixed deflection (representing an average correction) is put on to the sight system. The correction is effected by arranging the sight, when setting for elevation, to move in a plane inclined slightly to the vertical and intersecting the vertical plane in a line parallel to the axis of the gun; thus the greater the elevation on the sight, the greater the automatic deflection imparted. This method of compensation allows of a convenient combination with the reciprocating sight, by mounting a transverse bubble in such a manner as to ensure that, when central, the body of the sight is tilted to the left at the required angle; but the open, telescopic or panoramic sights are mounted on the rocking portion so as to have true verticality when the bubble is cross-levelled. Thus the cross-levelling gear neutralizes any want of level, and permits drift to be corrected for by movement of the sight in a tilted plane when setting for elevation; but the range-scale must be graduated to register elevation in a vertical plane.

In the system of independent line of sight in use with certain light field carriages the two parts of which the quadrant angle is composed—the angle of sight and the tangent angle—are applied to the gun independently and by different men. This system necessitates an intermediate component carrying the sight, and two elevating systems, the lower of which elevates the intermediate component, sight, cradle and gun for angle of sight, and the upper elevates the cradle and gun for tangent angle. Thus, conjointly, the two elevating gears give the quadrant angle. A sight clinometer is fitted to the sight to register the angle of sight for indirect laying, whilst a range-indicator, operated by the upper elevating gear, registers the tangent angle. Once the sight has been aligned on the target, the tangent angle may be altered to correct the range without disturbing the layer for direction. Such a system is useful when firing at moving targets, the direction and elevation having to be altered simultaneously, but it has a disadvantage in that it is difficult to apply the reciprocating principle when the gun has to be moved independently of the sight. Drift is usually corrected for by inclining the trunnion axis. The latest method of securing this principle, though not truly "independent," combines the reciprocating sight with an automatic drift correction.

The rocking-bar sight is mounted on a pivot which is always parallel to the gun axis, and thus can be rocked laterally under the control of cross-levelling gear to maintain verticality, which is indicated by a transverse bubble. An acorn-pillar, or front sight, and notched leaf, or rear sight, are fixed at the extremities of a sight-bar which is mounted on a vertical pivot on top of a rocking-bar; the rocking-bar is pivoted transversely at the front of a sight-carrier attached to a support on the cradle. The sight is set for elevation by means of a worm and arc-pinion drive in mesh with an arc on the rocking-bar, the range or tangent-angle being registered on a drum fixed to the pinion-spindle. The pivot of the rocking-bar is inclined so as to give an approximate drift correction at all ranges. To give deflection, the rear of the sight-bar is fixed to a nut mounted on an endless screw carried at the extremity of the rocking-bar; the nut traverses across a degree scale fixed to the rocking-bar. Bearings for a telescope are fixed to the sight-bar.

A sight clinometer is usually fitted to the rocking-bar so that, if necessary, the sight can be set first for angle of sight and subsequently for tangent angle. In effect, the clinometer is an adjustable spirit-level. A bubble is mounted in a sliding segment having worm-teeth cut on a curved base; the segment is moved relatively to a carrier by a screw mounted in the latter and in mesh with the teeth. Degrees of elevation or depression are registered on the face, while the screw is fitted with micrometer head to read minutes.

The employment of muzzle-velocity correctors for use in conjunction with the range drum is becoming general. The corrector (not to be confused with the "corrector" employed for varying the height of burst of time fuzes) also provides means for determining the muzzle velocity from firing at a known range, allowances being made for standard conditions; sights so fitted are known as calibrating sights. The corrector, which may be attached to the oscillating bracket or to some part of the range-gear in independent-line sights, fits over the face of the range-drum and is graduated in ranging muzzle velocities; a knife-edge reader, hinged at one end, has the other end attached to a nut mounted on a screw in the corrector and engraved with an arrow for reading the muzzle-velocity scale. The knife-edge reads the yard-scale graduations, while fine adjustment along the muzzle-velocity scale is ensured by the nut-and-screw arrangement. The yard-scale is engraved upon a spiral designed in conjunction with the muzzle-velocity scale to give the correct tangent angle for the muzzle velocity used.

FIG. 2

With certain carriages it is inconvenient to mount the sight on either the trunnion or the cradle. In such cases the sight is mounted upon a pivot on the intermediate carriage, the sight-carrier being constrained, by means of parallel link-motion gear, to make the same angular movement as the gun. For the sight to be effective, the parallelogram must be correct, and adjustments may be required for the lengths of the link and the arm. In certain designs the independent line of sight is obtained without the use of an intermediate component, and combined independent-line and reciprocating sights are also in use.

The automatic sight is discussed and an example illustrated at 25.64; here, therefore, it is sufficient to recall its basic principle, which is, that for a gun mounted on a level platform at a fixed height above mean sea-level, there is only one angle of depression of sight and one quadrant angle for any given range. Thus, if the sight be pivoted transversely to the cradle and made with an arm projecting downwards from its front end, there is, for a given quadrant angle, one position only for the lower extremity of this arm; if the arm be caused to engage with a suitably cut cam fixed to the intermediate carriage, any quadrant angle on the gun will impart the correct sight-depression to the sight.

A distinctive feature in connexion with all anti-aircraft sights is the necessity for an automatic reduction in the tangent angle for a given range as the angle of sight and quadrant angle increase. Consequent on the varying range, height and speed of aerial targets, large corrections have to be applied to compensate for the vertical and lateral angular movements of the target; these corrections inter-

to complicate further the design of an efficient sighting system. No description of such a sight, therefore, is possible within the limits of this article. For reasonable accuracy of fire, the mounting must be level. Anti-aircraft mountings are generally fitted with ranging arcs; in some cases a second set of indicators is fitted to enable horizontal ranges and quadrant angles to be used. A sighting system which also embodies the principle of the independent line of sight has been tried in the British service.

The panoramic sight is used with field ordnance for indirect laying for direction, from a position out of view of the target. The layer is enabled to take advantage of any auxiliary aiming-mark and to lay without exposing himself. The sight may be used also or direct laying.

A typical panoramic sight is shown in fig. 1. It is a prismatic telescope mounted in a vertical tube having a rotating hood at the upper, and a horizontal tube at the lower end; the hood is mounted on a horizontal graduated dial-plate with which it may be revolved through a complete circle, by worm-gearing; the

FIG. 1

which is seen on the cross-lines of the diaphragm, the latter being illuminated by a plain window let into the horizontal tube.

Other forms of dial sight are, the simple graduated and flexible dial fitted with an open sighting-bar; and the *collimator*, which exists in several forms. In principle an eye-lens and ground-glass window are mounted at the ends of a tube, an arrow or cross on the window being at the principal focus of the lens. With one eye applied near the lens, the cross will be seen, but there is no vision beyond the cross due to the ground-glass; the other eye sees the aiming-point. The gun is traversed until the cross appears superimposed on the aiming-point. Both eyes are used, and are viewing approximately parallel rays. Unlike ordinary open sights, there are not three points at varying distances to be brought simultaneously into alignment, but the eyes view two points under practically the same conditions.

Sights for Rifles and Machine-Guns.—The improved ballistics of rifles generally, on the one hand, and the shortening of the sight radius due to shortening of the barrel, on the other, have made the question of better sights a very urgent one. Attempts to retain the old sight radius by bringing the rear sight closer to the eye resulted in the discovery that it was impossible effectively to use an open sight nearer than twelve to fourteen inches from the eye (owing to the inability to focus on rear sight, front sight, and target at the same time) and led to the reintroduction of the aperture or peep sight, in itself an old invention. In this the rear sight is placed close to the eye, and no attempt is made to focus on the aperture. The

eye looks through the aperture and instinctively centres the front sight. Any blur around the aperture will not impair the accuracy as it is equal on all sides of the opening. If the eye is now focused on the target, the front sight is at sufficient distance to afford very good definition. Another advantage is that the accuracy of the sight is not affected by slight changes of light.

Aperture sights are of two general types: the disc aperture consisting of a large disc, which shuts off all view of the target except that seen through a peep hole of from .03 to .06 in. in diameter; and the Lyman type which has a thin rim with peep hole about .010 in. in diameter. Disc sights, which are used principally for target shooting, are unsuitable on account of their limited field for moving-targets, or where quick aiming is required.

In the Lyman type the entire target and its surroundings may be seen while aiming; it may be used in poor lights where open sights cannot be used, and moving objects may be quickly aimed at. The sights on the British 1914 rifle (U.S. Rifle Model of 1917), and the Browning automatic rifle are of this type (fig. 3). The aperture (a) is 0.1 in. in diameter, and is made through a disc of about twice the diameter of the aperture. The battle-sight¹ is vertical and in use when the leaf sight is flat and vice versa; the sizes of aperture and ring are the same in both. This sight was found very satisfactory during the World War. It has no lateral adjustment, service experience having shown that the sights were satisfactory without this refinement. An aperture 0.1 in. in diameter is thought by many to be too large, .070 in. to .080 in. being the size most favoured. The U.S. 1903 Rifle (Springfield), and the now abandoned Ross rifle are the only other military rifles with an aperture sight. In the case of the Springfield, which has also sight notches of the usual type on the slide, it is found that, although the aperture is very small (.005 in.), and too far from the eye, it is always preferred to the V. for fine shooting. The superiority of the aperture sight over the open sight is in fact now generally admitted. It is almost universally used by rifle experts, and the delay in its general adoption for military use is due to the impracticability of effectively and cheaply applying it to rifles now in existence.

Optical rifle fore sights designed for use with aperture rear sights have recently been placed on the market. These sights consist of a dioptric convex lens of magnification of about 2½ diameters, with a spot or ring in the centre for use as a bead. The lens when viewed 3 or 4 ft. from the eye gives an upright magnified image of distant objects. An aperture rear sight, preferably of the disc type, with an aperture of 0.03 to 0.04 in. diameter, or a lens rear sight should be used. Better definition as well as magnifying power is claimed for these sights.

Luminous sights for night use have been experimented with and used to a limited extent on machine-guns and rifles for military purposes. These sights, as a rule, consist simply of metal sheaths which slip over the front sight and rear sight and have suitable containers for the luminous material used. For periscope sights see RIFLES AND LIGHT MACHINE-GUNS.

Telescope sights are often applied to sporting rifles and military rifles used for special purposes. These sights consist of a telescope with a reticle for aiming which takes the place of a front sight. The magnification is usually from 2.5 to 6 diameters; those from 2.5 to 3 power are considered the best for general purposes as they give a larger field and can be used in poor light. Adjustments for range are made either by moving the crosshairs only, as in most German rifle telescopes, or by means of holding brackets with adjusting screws which give both vertical and lateral adjustment; the latter type being more accurate. The advantages claimed for telescopic rifle sights are that they permit more accurate aim by magnifying the errors of holding the rifle, also that they allow objects to be seen more distinctly, particularly in a poor light. The latter is probably their greatest advantage; their superiority to a good aperture sight not being as great as is popularly supposed.

The Vickers and Browning machine-gun sight embodies the principal small-arms-sight developments of recent years. The slide, which is made to travel obliquely in the leaf to compensate for drift, has a revolving disc with apertures of various sizes which may be used for different ranges and light conditions. A fine adjustment for elevation and a windage adjustment are provided, also an open battle-sight. The fore sight is a blade, open or hooded.

The Lewis gun has a simple tangent aperture sight without drift or windage adjustments, but with a vertical adjusting screw for fine adjustments in elevation. The sights used for direct fire on Continental European machine-guns are all of the open type and are usually without correction for either drift or windage.

Tubular sights, which consist simply of a straight piece of tubing, are used to some extent on tank machine-guns, as these sights only require a very small opening in the armour plates for their effective use. The latest tendency, however, is to provide tank machine-guns with a telescopic sight of special construction.

Anti-aircraft machine-gun sights, which compensate for the drift and trajectory of the bullet and offset the speed and direction in

¹ A battle-sight is one which requires no adjustment for distance, or rather is permanently set to a certain range, inside which the bullet in its flight never rises more than a man's height above the line of sight.

which an aeroplane is travelling, were brought into use during the World War. One of these is illustrated in fig. 4, showing a design used by the British and U.S. armies. This consists of a slide having an aperture 0.25 to 0.5 in. in diameter and fitting on the regular back sight leaf. The aperture (b) is set at a given height for a standard range. The shapes of the ellipses are proportional to the actual horizontal sections of a cone of fire from the gun at a given height and elevation. The design of the outer oval (a) is based on an assumed angle of gun elevation of 50°, height of target about 1,000 ft., and a speed of plane of 100 m. per hour; that of the inner oval, on an assumed angle of gun elevation of 15°, a height of 250 ft., and a speed of 120 m. per hour. The middle figure shows the correct firing position with the hostile plane central as viewed through the rear and front sights; that on the right shows a plane at close range flying at an angle with the gun position and perpendicular to the axis of the bore; and that on the left shows the target at a greater range and at an angle with the gun.

(H. O. L.)

FIG 4

The Panoramic Machine-Gun Sight.—The use of machine-guns for indirect fire during the World War was followed by the demand for instruments for obtaining data and laying the guns. This demand led to the production of many devices, some of which were well fitted for their purpose, and some of which were make-shifts. But, as the war progressed, it became apparent that indirect fire was becoming increasingly important, and an attempt was made to produce one high-grade device that would replace as many instruments as possible. This effort, in the case of the United States, resulted in the production by the Ordnance Department of the panoramic machine-gun sight, described below. At the same time, all Browning machine-guns were fitted with a bracket on the left side which was designed to carry the panoramic sight and also to furnish on its upper surface a flat space for applying the clinometer.

The illustration (fig. 5) shows the panoramic sight in place in its bracket on the Browning machine-gun. The sight consists of a X6 prism telescope capable of movement in elevation and azimuth (360°). The movements of the sight are controlled by means of graduated knobs. The lower knob is for movement in azimuth (deflection), and a quick release is furnished to enable large changes to be made quickly. The upper knob controls the vertical movement of the sight. This knob has two sets of graduations. One of these is for ranges, and the second, which is on a ring-sliding friction tight on the knob, is for vertical angles, above or below the horizontal (angle of site). The telescope is provided with a spirit-level which is parallel with the axis of collimation. This instrument is used on the same principles as the panoramic sight of artillery, to measure angle of site and to lay the gun on a visible or invisible target. The telescope has, besides the usual cross-lines, graduations showing both vertical and horizontal angles, and also a vertical scale resembling an inverted sight leaf, which is employed for the correction of fire when the strike of the shots can be observed. The sight can also be used separately from the gun (in combination with a compass and a tripod of non-magnetic metal) for the same operations as those performed by the artillery director.

(J. S. H.A.)

SIGNAL SERVICE, ARMY (see 25.71).—In the ten years that elapsed between the Russo-Japanese War of 1904-5 and the outbreak of the World War in 1914, evolution in military signalling was rapid, both as regards organization and as regards instruments employed. The old principle of deliberate crudity of means, based on the idea that no refined instruments could be relied upon to survive the rough conditions of war employment, was giving way to a sense of the great possibilities opened up by modern science as applied to army signalling, while, in tactics, the ever-increasing tendency towards articulation of forces and distribution in depth was forcing the problems of liaison more and more into the foreground. But such evolution as there was in the period 1904-14 was naturally slight indeed compared with that which took place during the World War, in which stabilized conditions of warfare and the concentration of the scientific talents of all belligerent countries upon war needs produced results, both upon the army signal system and its instruments, that amounted to a revolution in the practice of war and, moreover, must affect profoundly the methods of intercourse between civilized nations in peace.

In the following article an account is given of the organization, working principles, and instruments of the signal service of the British army in the World War, and of some of the more notable features of signal practice in other armies.

(1) **Definition and Duties.**—The signal (intercommunication) service of a modern army is responsible for the maintenance of efficient intercommunication between all branches, departments, formations, and units of the army. Intercommunication within units, other than signal units, is usually provided by means of regimental signallers, but the officers of the signal service exercise supervisory control here also. The signal service bears the same relation to the army of which it forms a part as does the nervous system to the human body. Its principal duties are:—

- (a) The transmission of information from the front to unit commanders and to the headquarters of formations.
- (b) The transmission of orders from commanders to their subordinates.
- (c) The maintenance of efficient liaison between infantry and other arms (such as artillery, air force, tanks, etc.) and between neighbouring formations.

For the efficient working of an army, means of intercommunication must be swift, certain, and, under the circumstances of modern war, varied. The system must be essentially simple and standardized to the greatest possible extent, yet capable of considerable expansion at short notice, and of modification to meet the most diverse conditions of warfare. Organization and working schemes must be elastic, and types of signal instruments must be devised to cope with all special sets of conditions that have been experienced or can be foreseen.

(2) **British Army System.**—Until the application of electricity to the long-distance transmission of messages, the intercommunication of armies was carried out mainly by means of visual appliances or by the use of message carriers. Liaison officers and orderlies have been used from the very earliest times; the arrow was frequently employed in mediaeval times for the transmission of information into and out of besieged towns; the pigeon was used with success, notably in the wars of the Netherlands against Spain; permanent lines of semaphore communication (masts with movable arms) were employed both by the French and the British during the Napoleonic Wars. Later, the invention of the Morse code and the adaptation of the semaphore principle to field signals led to the general employment of flags, lamps and, later, of the heliograph. The field telegraph made its appearance in the middle of the 19th century, and in the last years of the century the field telephone came into use. Lastly, in the Russo-Japanese War of 1904-5 wireless telegraphy came on the scene.

In 1911 the British "Signal Service" was constituted as a distinct branch of the Royal Engineers. At about the same time, the adoption of the buzzer telephone as a standard army instrument and the employment of the motor cyclist as a message carrier placed two new methods of intercommunication at the disposal of the signal officer. The outbreak of the World War in

Aug. 1914 found the Expeditionary Force equipped with a signal service controlled by a director of signals on the general staff at G.H.Q. This service included a signal unit at G.H.Q., a lines-of-communication signal company, and a signal company with each corps and each division. Artillery intercommunication was, however, entirely a separate matter for which that arm itself was solely responsible. So also, was intercommunication inside the infantry unit; and the absence of a chain of command within the signal service itself (each unit commander being responsible only to his own general staff) caused a looseness of organization which soon showed itself to be a grave defect. The means of intercommunication employed were those already mentioned, viz., telegraph, telephone, flag, lamp and heliograph, with the addition of wireless telegraphy, which was, however, at this time adopted only for the special requirements of the far-ranging cavalry division, and consisted only of one lorry and a few wagon and pack stations, all of rotary spark type. (The power of the stations was 3, 1.5, and 0.5 K.W. respectively; the range, when working to stations of similar type, 100, 80 and 30 miles.)

The signal organization summarized above proved adequate to deal with the mobile conditions of the first few months of the war. These early days were specially notable for the triumph of the motor cyclist. Telegraph and telephone, visual and orderlies, and mounted liaison officers also played useful parts, and it was not until position warfare set in in the winter of 1914-5 that further changes were found to be required. Then, however, the desire for, and the possibility of collecting, a greater quantity of more exact information (especially for artillery observation) led to a considerable increase in the complexity of the army signal organization. To the exigencies of position warfare may be attributed almost all the evolution in signal implements and signal organization which marked the course of the war. The chief alteration in signal policy, on the other hand, was brought about not so much by position warfare as by the resumption of semi-mobile and mobile warfare which took place to a slight degree in 1916, to a slightly greater extent in 1917, and completely in 1918.

The principal result of "stabilization" was naturally an immense increase in the number and weight of the guns employed. Both for offensive and defensive purposes massed artillery became the weapon of paramount importance, and this had two principal effects on the forward signal service. The fire of the large number of guns employed could not be effectively directed without a greater measure of intercommunication; while at the same time, intercommunication in the region subject to heavy gunfire became more and more precarious.

The extra intercommunication required was supplied by a rapid increase in the number of telephones in use at observation posts and at artillery headquarters. The need for intimate liaison between infantry and guns led to a similar increase at infantry headquarters.

The magneto telephone came into use for the first time forward of corps headquarters, and, once the superior convenience and efficiency of the instrument were recognized, the demands for its installation increased so rapidly as to tax the signal service to its uttermost capacity. A new danger at once arose and threatened to wreck the whole intercommunication service. The tendency was to concentrate all available energies on the installation of telephones and the laying and maintenance of telephone lines. All other means of signalling lost their proper proportion, and an inefficient telephone service was soon in a fair way to become the only means of intercommunication throughout the whole army. Such an undesirable result was only prevented by the incidental troubles arising from the indiscriminate laying of lines. In effect, it was the "overhearing" menace, which will be referred to later, that, together with the prevalence of induction trouble and the difficulty of making "safe" the forward lines, proved to the signal service and to the commanders it served that it was unwise to stake everything upon one method of intercommunication.

The difficulty of maintenance of forward intercommunication was overcome partly by the adoption first of shallow and subsequently of deep buried cable; partly by the evolution of various new alternative methods of signalling; partly by the perfection

and adaptation of methods which had temporarily fallen into disrepute under the new conditions.

In 1915, cables were buried 2 or 3 ft. deep and by this means temporary immunity from shellfire was gained; in 1916, the general adoption of the 6-ft. bury (while it saddled the signal service with endless labour problems) successfully solved the difficulty of the maintenance of an efficient forward telephone and telegraph system. One inevitable consequence of the adoption of the "bury" was the concentration of the forward lines into a few main routes, thus paving the way for the great reform in policy which was later brought about under the pressure of rather different circumstances.

The induction which resulted from the collection of 20 to 100 circuits in these main corps and divisional routes was reduced to a slight extent by the general substitution of the sounder for the vibrator in forward units¹ and by the elimination of the buzzer as a general means of intercommunication. It was later almost entirely overcome by the adoption of metallic circuits of twisted cable² for all forward lines.

Mention should be made of the alternative methods of signalling which underwent their first main period of evolution in 1915. In 1914, the weight and accuracy of modern artillery fire had caused visual signalling to fall into disrepute as being too dangerous. It was soon found, however, that the lines which were at that time the only general alternative to forward visual signalling, were also untrustworthy, and that salvation lay in employing as many alternative means as possible and therefore in improving all available methods as well as evolving new ones. Visual was rehabilitated by the invention of the inconspicuous signalling disc and shutter, by the general adoption of "D.D. D.D." working (signalling from front to rear without reply) and by the adoption of the efficient electric signalling lamp in place of the more conspicuous and noisy Begbie oil lamp which was the standard equipment at the outbreak of war. At the same time the use of pigeons as message-carrying agencies was revived, and wireless telegraphy began to be adapted to forward work. The former were first used by the Intelligence Corps towards the end of 1914, when the British were operating in a district noted for its pigeon fanciers. From this small beginning grew a service which at the Armistice numbered over 20,000 pigeons, while no less than 90,000 men of all arms had been trained to handle the birds. Lofts were kept usually on a line passing about through divisional headquarters and pigeons were forwarded by motor cyclist and taken into the trenches by selected pigeoners. Here they remained until required for use or until 48 hours had elapsed, when they were released with or without messages.

Wireless telegraphy for the forward area was first attempted in the summer of 1915, when experiments were carried out which resulted in the standardization of two types of set, the 120-watt (Wilson) and the 50-watt (British field) set. The former was intended for work at divisional and corps headquarters and consisted of separate transmitting and receiving apparatus. The spark transmitter received its energy from a 26-volt accumulator through a small motor-driven interrupter fitted in the set itself; its original complement was a crystal receiver specially designed for the short waves (350, 450, and 550 metres) on which the forward sets were obliged to work. The 50-watt set, on the other hand, was a combined transmitter and receiver, the transmitting

¹ The two telegraph instruments, the sounder and the vibrator, are worked on entirely different principles. In the former case the currents used rise to their full value very rapidly and then remain steady a comparatively long time. On the vibrator system, on the other hand, the currents used are constantly altering in value and even changing in direction, the vibrations being at an audible rate of frequency (several hundred per second). It is these latter rapidly alternating currents which set up rapidly alternating EMF in the earth surrounding the conductor and provide the ideal conditions for overhearing at a considerable distance. A buzzer is a particular type of instrument using "vibrating" or "alternating" current.

² In a telegraph circuit consisting of two wires laid side by side, the electromotive force set up around one conductor will be neutralized by that set up around the other in which the current is travelling in the opposite direction. The most efficient disposition of such neutralizing cables is naturally that where the two halves are most intimately interturned, as in twisted cable.

portion of which was energized by the current from a 10-volt accumulator. It was intended for work in posts close to the front line and at brigade and battalion headquarters and the complete station with its two 15-foot masts could be carried by a party of three men. Both types of set fulfilled their original purpose admirably. They remained the standard wireless sets for forward infantry command intercommunication purposes throughout the war, and have only gradually been superseded by the continuous-wave wireless sets which are now the standard sets for practically all purposes.

Other wireless sets which were evolved during the war, which owed their invention to the same necessity for indestructible and invisible alternative means of forward intercommunication, were the loop wireless sets. These were sets of short fixed wave-length (66 and 80 metres respectively) which were arranged in two complementary installations—a "forward" and a "rear" station to each set. The forward station was distinguished by the possession of a rectangular aerial of folding tubing which could be erected wholly below the surface of the ground in a deep trench or in a dugout, thus rendering the station invisible and often invulnerable. The rear station had a short wire aerial, much of the type used with the standard "British field" (50-watt) set. It was intended, as its name suggests, for work at places not in the direct observation of the enemy. These sets with slight modifications, remain in use at the present day for intercommunication within the infantry battalion.

At least as important as this evolution of alternative methods was the consolidation and reorganization of the signal service which took place during the years of position warfare.

For the understanding of the present organization of an army signal service some account of the effect of the interaction between the requirements of the general staff and the unfamiliar war conditions experienced in the years 1914-7 is essential. Whereas in the pre-war organization of the signal service the ruling consideration was mobility, a military situation arose within six months of the declaration of war, and continued for three years, in which extended movement was the exception and not the rule. The effect on the signal service was a multiplication of the calls for intercommunication made upon it and at the same time an increase in the unreliability of all means of forward signalling. Work in the danger zone had usually to be done not once but many times; duplication of routes forward, first of brigade, and then of divisional headquarters, became essential. At the same time, the demands of the staffs, of the unit commanders, and especially of the artillery, increased manifold.

An establishment adequate to the demands of mobile warfare could not possibly cope with those of position warfare. The small degree of supervision and absence of coördination, due to the practical autonomy of the signal service within each formation, which had been recognized as drawbacks in the manoeuvre warfare of 1914, became impossible obstacles to efficiency in 1915.

The first reforms which enabled order to be wrought out of the chaos into which forward signals were in danger of falling were—(1) the vesting of the control of all forward signals in the hands of the divisional signal company commander and (2) the assumption by the signal service of responsibility for, and a measure of control over, artillery signals. By this means it proved possible towards the end of 1915 to eliminate unnecessary lines and to insist on the reeling-up of derelict cables. At the same time steps were taken to supplement the obviously inadequate personnel.

The original signal service units of the British Expeditionary Force of 1914 had consisted essentially of (a) the personnel to man one or at most two headquarters offices; (b) sufficient cable or airline detachments to lay one main route to all subordinate formations or units then considered to be entitled to telephone or telegraph; and (c) a few despatch riders, orderlies, and visual signallers. This establishment only just sufficed for the skeleton intercommunication system required in a mobile army, and neither office staff, line-building detachments, nor orderlies, were sufficient to man the greatly swollen system of position warfare. Reinforcements were essential, and not only reinforcements but radical reorganization as well. Much of the personnel required

was for the maintenance of heavily shelled, long divisional and corps lines through the danger area. If these routes were to be efficiently maintained and circuits allotted with due regard to the relative urgency of individual requirements, the men manning them must remain at their posts irrespective of divisional moves. This meant the formation of pools of area-maintenance personnel and units at corps or army headquarters and the creation of these pools was one of the main features of signal reorganization during the position-warfare period. Individual increases to the mobile portions of units also took place, corresponding to changes in signal methods (all in the direction of increased complexity) or alterations in procedure (e.g. the assumption of responsibility for artillery and machine-gun signals) which applied equally in position and in mobile warfare.

The increases in the strength of signal units during the war are indicated by the figures in the annexed table, which gives the strength of the signal personnel in an army of two corps, each of three divisions, in 1914 (when the only equivalent of an army signal company was the G.H.Q. signal company) and in 1918, respectively.

Strength, 1914, at Mobilization.

Unit	Each		Total	
	Off	Other Ranks	Off	Other Ranks
G.H.Q. signal company	5	75	5	75
Two army corps H.Q. companies	4	63	8	126
5 airline sections	1	57	5	285
8 cable sections	1	35	8	280
6 divisional signal companies	5	157	30	942
Total personnel			56	1708

Strength at Armistice, 1918.

Unit	Each		Total	
	Off	Other Ranks	Off	Other Ranks
One army signal company	15	340	15	340
2 cable sections	1	34	2	68
3 airline sections	1	43	3	129
8 area signal detachments	1	13	8	104
One signal construction company	3	113	3	113
One light railway signal company	1	61	1	61
9 army, field artillery brigade sig. sub-sections	1	19	9	171
17 heavy artillery group sig. sub-sections	1	28	17	476
Two corps signal companies	6	105	12	210
4 airline sections	1	43	4	172
4 cable sections	1	34	4	136
Six divisional signal companies	15	400	90	2400
Total personnel			168	4380

While the above description applies principally to the evolution of organization in the general signal service, some special mention of the alterations which took place in wireless units is necessary, particularly since wireless telegraphy will in all probability play a more dominant part in the intercommunication service of the army of the future. The few wireless sets which were in use in the British Expeditionary Force at the outbreak of war were manned by personnel who were all incorporated in a single "wireless section" which shortly became a "wireless company." The first great increase in the value of army wireless came with its application to intelligence purposes, originally for the simple interception of enemy wireless messages, and then also for the location of enemy wireless sets whether in the field, at sea, or in the air. For this latter use of wireless alone—"position finding"—many special sets were devised and a numerous personnel collected in special intelligence wireless units.

Next, the invention and perfection of the portable "trench" wireless sets in 1915 and 1916 created a further demand for wireless personnel and increased the already swollen establishment of the central "wireless company." The result was a measure of devolution and the formation of an army wireless company in each army. The commanding officer of this unit acted as staff officer for wireless to the chief signal officer of the army, and was

responsible for the organization and practice of wireless within the limits of the army.

Yet another direction in which wireless personnel found employment was in the detection and prevention of the indiscretions which, in 1916 particularly, enabled the enemy to glean important information by listening to the traffic over the British telephone system. It was in 1915 that this menace first became important and in the following year "overhearing" became so serious that the forward telephone service was stultified. Many important results followed, directly, or incidentally. Of these may be mentioned:—

- (1) The general adoption of closed metallic circuits everywhere within 3,000 yd. of the front line.
- (2) Alterations in the system of identification calls.
- (3) The replacement of the buzzer telephone by the fullerphone in the forward area.
- (4) The invention of the screening buzzer, a powerful vibrator used for drowning all sounds carried forward by induction from the front line.
- (5) The invention and perfection of the 3-valve listening sets and the formation of detachments of the army wireless companies to work them.¹
- (6) The growth of an organization for the interception of speech on enemy lines and the policing of our own telephone system.
- (7) The application of earth induction telegraphy to signalling which resulted in the invention and evolution of the power buzzer.
- (8) The increased employment of alternative methods of signalling (visual, wireless, etc.) so obviously liable to overhearing or overseeing that they were used with caution.

It is difficult to decide which of the many results was the most important, but perhaps the most interesting from the present point of view was the evolution of the power buzzer. This was a powerful vibrator worked by the current from a 20-volt accumulator, and connected to inconspicuous earths of insulated wire which could, if necessary, be buried 6 ft. deep with little labour. It occupied a place in position-warfare signals for which no other instrument, except perhaps the loop sets which lately more or less superseded it, was suitable. Detachments of troops isolated by the enemy could send out code signals which could be picked up by listening sets, themselves inconspicuous, at ranges up to

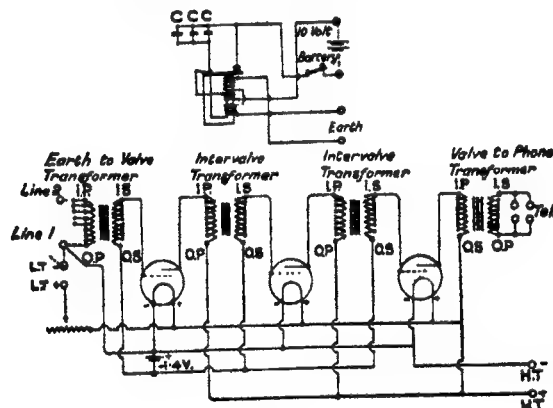

FIG. 1.

3,000 yd. On several occasions of importance these sets remained the only means of communication with and from units that had advanced rapidly in attack, or become isolated in defence.

The diagrams in fig. 1 show the principles of the power buzzer amplifier system. The transmitter (a) is a powerful buzzer taking its current from a 10-volt accumulator. When the Morse key is pressed,

¹ The early overhearing experiments were made with ordinary telephone receivers and results, while they pointed out the danger, were not very satisfactory. In the German, French and British armies, it was the discovery of the possibility of using the new 3-electrode valves for magnifying extremely small changes in electric potential which at the same time raised the "overhearing" menace to its greatest pitch and caused the development of large branches of "Intelligence" and Signals to deal with this new branch of scientific warfare. The valves were used in receiving circuits both as detectors and amplifiers and revolutionized both telephony and wireless telegraphy.

a current from the 10-volt battery flows through the key to the upper contact, across to the lower contact, along the armature, thence along the primary coil, and back to the battery. The current magnetizes the coil which attracts the armature, thus breaking the contact, and allowing the armature to fly back and remake contact, etc. Each time the primary current is thus completed and broken, currents in the opposite direction are induced in the secondary coil and are passed to earth through shut lengths of cable and earthpins. Condensers, as shown, are connected across the break to reduce the sparking to a minimum.

To obtain the best results in two-way working a three-valve amplifier (b) is employed. The currents, received on similar earths, pass through the primary circuit, are induced into the secondary of the earth-to-valve transformer which is connected to the grid and, through a single dry cell, to the filament of the first valve. The amplified signal from the first valve passes through the second and third valves and, finally, the three-amplified signal passes through a valve to telephone transformer with ordinary wireless receivers in series with the primary winding.

With all these developments, and especially with the rapid increase in the number of listening sets, the wireless service, as a separate entity, was becoming unwieldy, and its absorption into the general signal service organization was essential to its most efficient administration. In 1917 and 1918, therefore, the army wireless companies were broken up, the section which had composed them being allotted to the divisional, corps, and army signal companies, according as they were equipped with portable trench sets, Wilson and listening sets, or the larger and more powerful Crossley motor sets used for supervisory and tactical work at army headquarters. In this form wireless organization survived the war.

The only change of moment in army wireless after this time was the application of the continuous wave system to army use. The early experimental sets made their appearance in 1917, but for some months they proved to be too delicate and untrustworthy for the work under the hard conditions of active service. Gradually, however, technical difficulties were overcome and more robust types of instrument devised. Before the end of position warfare, portable 30-watt continuous wave sets of about the size and portability of the 50-watt spark sets, but with forward aerials only 4 ft. high and a normal range of 12 m. were doing good work with heavy artillery observation stations. The Armistice in Nov. 1918 found continuous wave wireless still chiefly confined to the artillery, but new and more powerful sets had already been devised and tested. Since that date, spark wireless has been entirely ousted from its former position except for the short-range loop sets—the successors of the power buzzer—which are retained for work within the battalion and similar small units working in the immediate vicinity of the front line. There seems little doubt that in the future development of army signalling, continuous wave wireless is likely to play an all-important part.

While the chief characteristic of the earlier position-warfare period was the evolution of signal implements and the adaptation of signal organization to stationary tactics, it was in the great battles of 1916 and 1917 that signal policy began to crystallize in very definite shape. The first result of the stabilization of the situation was the running forward of lines in all directions to serve the multifarious units which now for the first time made good their claims to telephone communication. Magneto and buzzer telephones and magneto, buzzer, and combined exchanges made their appearance in all formations from brigade rearwards, and buzzer telephones and exchanges were issued to battalions and batteries. The lines to serve these telephones and exchanges had in many cases to be duplicated and even triplicated, and a festoon of lines, converging from front to rear, or stretched transversely and at all angles across the front, hampered movement and defied the utmost efforts of the signal personnel whose business it was to maintain them. The necessity for economizing signal personnel and for the protection of lines alike tended to bring about two reforms. On the one hand, control was vested in the signal officers of superior formations; on the other hand, by their orders, all circuits were concentrated into a certain limited number of well-defined main routes.

The first of these reforms in point both of importance and of time was the rearward movement of the centre of gravity of the

command of forward signals from the uncontrolled battalion, through brigade, division, and corps, to army. Concurrently with this, the commanders of signal units became staff officers—i.e., representatives of the command itself—instead of simple executants.¹

In the meantime, the idea of the central signal route in each formation having been launched, it was natural that other means of signalling should at once tend to concentrate along these routes, with their protected test-points and signal offices. Economy and greater trustworthiness at once followed, and in the battle of the Somme, 1916, when the British army first carried out a great offensive from prepared positions, the central signal route, running from front to rear of each divisional sector and reinforced with all possible means of intercommunication, was attempted as a definite policy. The line system was carried forward in 6 ft. buries to a cablehead in, or even in advance of, the front line. Cable detachments were organized and held in readiness to extend the lines. Runners and despatch riders were organized in relay posts along the cable route. Wireless and power buzzer sets were also erected in convenient dugouts close to cablehead and the forward communication centres. By this concentration of means along one line, and by an all-round training which made the personnel to some extent interchangeable, economy of personnel, elasticity of procedure, and a minimum of casualties were ensured.

In the more extended offensives of 1917, this principle was carried still further and reinforced by instructions issued by G.H.Q., which required the headquarters of formations to give the signal officers concerned early and detailed information as to projected operations, forbade movements of headquarters without good cause, and laid down other important points of principle.

The culmination of position warfare thus arrived in the spring of 1918 to find the signal service quite equal to the calls made upon it. At G.H.Q. and on the lines of communication were adequate office staffs and a sufficient number of permanent line and airline construction companies and sections. The bases, camps, depots, and stores concerned with the administration and supply of a great army were served by army telegraph and telephone routes. Maintenance parties at all offices dealt with ordinary day-to-day repairs; breakdown gangs at central positions were in readiness to cope with the catastrophic breaks due to bombing and long range shelling. At G.H.Q. itself powerful wireless stations formed the initial link of a chain line which reached right forward to the front line; other stations were engaged in intercepting the German wireless; and a headquarters wireless staff coördinated the activities of the Intelligence stations scattered throughout the rear army zone. Here, also, was the nerve centre of the whole signal service in France—the directorate of signals—the staff which formulated the policy of the service, supervised its organization and working, and allocated the incoming reinforcements of men and material.

The basis of the signal system of the army was again a telegraph and telephone network which was built up on a "chessboard" or "grid" system, that is with front-to-rear routes and routes transverse to the front, spaced at regular intervals and with the main signal offices and test-points at the junction of the two. Until late in 1917 the approved theory was to make the line system approximate as nearly as possible to the perfect "grid" with as few and as heavy routes as possible. With the increase in the amount of long-range shelling and bombing which was a marked feature of early 1918, this principle required considerable modification. Two or three parallel routes usually took the place of the single heavy route of each corps or army area, and all routes were diverted to a much greater extent in order to avoid centres likely to be bombed or shelled.

The constitution and working of the army signal company perhaps more nearly reflected the conditions of position warfare than did that of any other. A telegraph construction company, a light railway signal company, and airline sections were the chief elements of the construction personnel, though there were also cable sections for connecting up isolated units at any time, and dealing with emergency connexions in battle. Here, also, were wireless light motor sections, mainly employed on supervisory duties, but like the G.H.Q.

wireless, available to take their place in the chain of intercommunication in the event of the failure of the lines. Most of the traffic was dealt with by wheatstone, duplex, and simplex telegraphy; and the magneto telephone, wireless telegraphy being chiefly utilized to assist and police the more forward stations. The chief signal officer of the army had also to coördinate the signal schemes of the formations in his army, and under his command were the area detachments whose permanent duty was the maintenance of the buried cable in the army area.

In the area of a corps—the forward position of which was liable to frequent shelling—the main routes were still permanent line and airline and the construction personnel consisted in the main of airline detachments. In addition, corps cable sections were available for emergency cable-laying, for loan to overworked divisions (a frequent case), for artillery signal work, or for running spurs to isolated offices off the main airline routes. The personnel of the corps cable sections was also often employed to supervise labour parties in the construction of the buried cable system, though, as above mentioned, maintenance personnel was provided through the army area detachments. The corps wireless section, while principally concerned with store distribution and supervisory and police duties, was more intimately connected with the tactical employment of wireless than was that of the army. Particularly in battle periods, the corps-directing station was frequently obliged to step in and assist its less powerful subordinates to attract the attention of other stations or to rebuke stations using undue power or contravening priority regulations, besides policing procedure and listening for occasional windfalls from forward German stations.

Lastly, the chief signal officer of the corps had to supervise and control the signal communications of the heavy artillery. For this purpose a special section had been added to his company, but this was altogether inadequate and in practice the whole energy of one corps cable section was usually devoted to the construction and maintenance of artillery lines. These corps units were differentiated in principle from the area detachments by the fact that they possessed sufficient transport to enable them to move forward while continuing their work. In all adaptations of the signal units of formations below army the essential characteristic of mobility was respected. Those elements of the service which required to be specialized to areas were embodied almost entirely in the army company, others being organized so as to be able to move as integers.

This principle of mobility naturally applied with still more force to divisional signal companies. Even when position warfare seemed to be most definitely established the retention of its horse transport by the divisional company was insisted upon, in spite of the extra work entailed by the care of horses upon a personnel fully occupied with its technical work. This insistence had its reward in the long run, for mobility regained all its old importance on March 21 1918 and retained it to the end of the war.

The original divisional signal company in 1914 consisted of the following elements—three "brigade sections" (in principle serving the infantry brigades), each of a telephone detachment and a squad of signallers, a "headquarters section" consisting of a small office staff and a few signallers and despatch riders, and a "No. 1 section" of three cable detachments, each of which was capable of laying 10 m. of cable and carrying three offices. By the spring of 1918 the "headquarters section" had been enlarged in every branch, and "No. 1 section" had been increased to four detachments to cater for the field artillery headquarters; but the "brigade sections," though much overworked, had remained practically unchanged. To these three original elements, however, others had been added. A small section, similar to a "brigade section," was serving with every field artillery brigade in the division. The reorganization of the machine-gun service in Feb. 1918 added another small section to serve the divisional machine-gun unit. The extension of wireless telegraphy to the division had involved the addition of sufficient personnel to man a "Wilson" and three "50-watt" sets and a charging set for accumulators. In addition, men were attached from brigades to man six power buzzers and their corresponding receivers, and to eke out the still undermanned visual detachments.

Forward of battalion headquarters, the direct responsibility of the divisional personnel ceased and, in battalions and batteries, signal communications were built and maintained by regimental signallers. Occasions occurred when the requirements of these units could be accommodated on the central system, but these were exceptional. Usually their signallers were fully occupied with the lines and with visual communication between the front line and their headquarters. The means at their disposal were light cable lines and enamelled wire with D3 buzzer telephones; heliograph, lamp, flag,² disc, or shutter; pigeon, messenger dog, message-carrying rocket and runner. In the case of power buzzer, pigeon, and messenger dog, communication was usually roundabout, via brigade, division and even corps headquarters; in the case of other appliances, direct touch from front line to company headquarters and from company to battalion headquarters was the rule.

The most interesting portion of the evolutionary history of signal communication in the war finishes with this period, and the story

¹ Strictly, this applies only to corps and army headquarters, though before the war ended, it was the unofficial practice in most divisions also.

² The artillery still used both Morse and semaphore; infantry signallers at this stage of the war were trained in Morse only.

of the remaining months of mobile warfare is that of the reversion to simple skeleton systems, based on the principle of the central route studded at suitable intervals with forward communication centres. No further radical reorganization took effect, the principal change being the gradual switching over from spark to continuous wave wireless for command intercommunication purposes.

(3) *Signals in Theatres of War other than France.*—While the greatest measure of evolution and adaptation naturally took place in the most important field and that nearest to the home sources of supply, almost every one of the outlying British theatres of war presented its special problems and emphasized the need of forethought and careful preparations, in respect of methods, personnel and stores alike, to suit local conditions, for instance in arranging for intimate coöperation with the intercommunication service of the navy in such operations as those of the Dardanelles, and the coastal operations of Sinai and Syria,¹ and in assigning an unusually large part to visual and wireless communications when a considerable water gap has to be spanned, as in the Dardanelles campaign. But perhaps the most significant lesson of experience in these campaigns was the greatly enhanced importance of wireless telegraphy relatively to other means of communication. Wireless plays a predominant part in such operations as those in E., W. and S.W. Africa, or those of the desert mounted corps in Palestine, which are conducted in vast, ill-developed theatres of war by comparatively small forces; for these frequently involve far flung troop movements in the offensive, and tactical isolation of detachments in the defensive.

The sets in use in the British Expeditionary Forces engaged in outlying theatres were the 3-K.W. lorry set; the 13-K.W. set mounted on a limbered wagon and drawn by teams of horses, bullocks, mules, or even men; and the Marconi pack set, a 0.5-K.W. set either carried in a limbered wagon, on pack horses or mules, or by bearers. The latter proved particularly valuable for work with flying columns of swiftly moving troops. All three types of set were spark sets deriving their energy from internal-combustion engines. In the future, these will doubtless be replaced by the more efficient continuous wave system of wireless, but they played their part well in the 1914-8 campaigns over ranges respectively of 120-100, 80, and 30-50 miles. The extreme case of isolation in the defensive is of course that of a garrison under prolonged siege, and as an example both of the utility of wireless telegraphy in this case and of the actual working output of even a small set, the case of Kut may be quoted. The only means of signalling possessed by the defenders of Kut for some weeks was a small wireless set. By means of this, touch was kept with the relieving forces until the surrender, 6,313 messages consisting of 434,861 words in 144 days being the final record of the set.

One other lesson learnt in the outlying campaigns may be mentioned—the special necessity, in the theatres far from home supply services, for standardization of implements and stores. This had only been partially carried out when the war ended, but since then a considerable reduction has been effected in the number of types of instruments in use.

(4) *Relation to other Arms.*—A subject of considerable importance is the relation between signals and other arms. Before the World War, the signal service was regarded by the general staff as an executive servant and by other elements of the army its existence and potentialities were too often slighted or ignored altogether. As the war went on, the importance of rapid, trustworthy, and copious intercommunication was emphasized more and more. The effect of this, in the gradual change in the status of the formation signal officer from the executive to the staff officer, has already been emphasized as one of the main features of the evolution of the service during the war period. Similarly, the relation of "signals" to intelligence, artillery, and even to infantry, has undergone a distinct change.

The intelligence service of all armies owes no small measure of its present effectiveness to the means provided by signals for tapping sources of enemy information. The listening sets; the position-finding wireless set; the interception wireless set; the

aeroplane wireless compass, are all efficient means of making out enemy plans and dispositions. So-called "wireless camouflage"² and the dissemination of false information by all means of signalling are well-recognized strategems.

The relation between artillery and the signal service is still more obvious. Efficient artillery fire was never more dependent on good observation than it was in the position-warfare battles of 1915-7, and observation is useless without intercommunication. As has been noted earlier in this article, artillery signal communication has become one of the definite functions of the signal service.

With the infantry, the signal service, through the regimental signal personnel which it supervises, has an equally close connexion, though the personal comradeship which is the basis of true liaison was made difficult, in the war, by the inevitable demands made on infantry labour for the burying of cables.

Signal personnel have frequently proved their ability to give a good account of themselves in infantry fighting, but it cannot be too strongly emphasized that the employment of signallers as infantrymen whether in the battalion, brigade, division, corps, or army, is a mistake except as a very last resource. The signaller is a valuable technical tradesman and he cannot be trained in a few days or even a few months. More casualties have probably been caused by lack of signallers, and therefore of the efficient signal communications essential to the guidance of the battle, than can ever have been saved by their employment in the fighting line.

No small amount of the attention of signal units, especially in position warfare, is now devoted to serving the needs of other technical branches of the army. Tank corps, royal air force, and survey battalions all made special demands upon the intercommunication service.

(5) *Means of Intercommunication.*—Details of the means of intercommunication employed by the British army signal service will be found in the official Manual of the Corps of Signals, Parts I., II., IV., and V. Some of the details of more general interest are given in the following few paragraphs.

Telephone and Telegraph.—The standard instruments in use are the telephone No. 110 (magneto ringing), the fullphone (buzzer call) and the telephone D Mk. III. (buzzer call). (In addition, a lineman's telephone is provided for the use of the intercommunication maintenance personnel which has both magneto ring and buzzer call.) Of the telephones, no special description is needed, their only peculiar characteristic being a robustness of structure and parts calculated to stand the rough usage of army life.

FIG. 2.

The fullphone is an instrument of peculiar interest. The chief cause of the leakage from telegraph and telephone circuits was the electrical stresses set up within the earth by the rapidly alternating current used. The fullphone is a telegraph instrument, the essential point of which is the changing at the receiving end of a steady current into an intermittent current of audible frequency, while at the same time the current in the line remains steady. A typical fullphone receiving circuit is shown in fig. 2. The interrupter (X) may be driven by any means, either electrical or mechanical. In army patterns it is driven electrically, being operated by means of a local cell.

If a steady E.M.F. is applied between line and earth and the circuit is closed at the interrupter, a steady current will pass through the choke coils (C1, C2), contact 2 and receiver. If the circuit is broken at X the current cannot pass through the receiver but will flow into the condensers (K1, K2, K3). When the circuit is again closed at X the condensers partially discharge through the receiver.

When the interrupter is working we therefore get an intermittent current in the receiver which can be made audible by adjusting the interrupter to run at a suitable speed, while the line current alternately runs into the condensers or through the receiver and remains practically constant and continuous in the line. The dots and dashes sent by the single current Morse key at the end of the line

¹ It was doubtless owing largely to the experience of these campaigns that steps were taken towards the end of the war to harmonize the signal procedure of the navy, the army and the post-office, that is, the form and manner of sending messages, the checks in accuracy, the ensuring of priority, and suchlike matters of technical detail that, in fact, are as important to efficiency as the design of instruments and the principles observed in their employment.

² Manipulating the technicalities and the volume of traffic of one's own wireless so as to mislead the enemy's interception service.

are therefore reproduced in the receiver as short or long notes. Readable signals can be obtained with about half a microampère, a main battery of one dry cell being sufficient. The employment of such an extremely small continuous line current eliminates danger of overheating, induction being reduced to a minimum.

In the rear areas, simplex, duplex, and wheatstone telegraphy are all used in the offices of the higher formations, which in the case of the armies may contain several hundred telegraph instruments and telephone subscribers. Magneto exchanges are the rule as far forward as brigade headquarters. At brigade headquarters buzzer exchanges are also installed and at battery and battalion headquarters buzzer exchanges are the rule. Circuits are of galvanized iron or copper wire beyond the limits of frequent shelling. Forward of this, main routes are of buried armoured cable (2-, 4-, or 7-pair brass-sheathed or iron-armoured usually) or light field cables which are standardized in several sizes in both single and twisted twin circuits. Enamelled wire, that is, wire roughly insulated by a coating of enamel, was used by forward troops during the war, but is now obsolescent.

Wireless Telegraphy and Telephony.—In all formations down to infantry battalions continuous wave wireless is now practically the only means used. There are three standard sets. For use at, or in rear of, army headquarters, or for long distances in mobile campaigns, a set is provided with a maximum range of 400 miles. The set has two 70-foot masts and is fitted to be carried either in a box car or a limbered wagon. (This is the equivalent of the former "heavy motor set.")

For distances up to 200 m. a smaller set is provided which has two 40-ft. masts and can be carried as above or on pack animals. For divisional work, the old "Wilson" and "British Field spark" sets have been replaced by a portable set with a range of 12 miles. This has two 15-ft. masts, is worked from accumulators or by a hand generator, and carried on pack animals or by bearers.

Finally, the loop sets already mentioned earlier are retained for work within the battalion and battery if required, though they are likely to be replaced soon by short range and short wave C.W. sets of much greater efficiency. The power buzzer and 3-valve amplifier sets are also available for use in case of position warfare.

Small portable wireless telephone sets for forward work have been devised, and similar sets were indeed used in the Air Force during the last months of the war. The sets are not yet standardized, but those in use have a range of some 2,000 to 3,000 yards.

Visual Telegraphy.—The visual instruments include the heliograph as used in pre-war days (see 13.223); the Lucas lamp; the shutter, and the flag. Of these, the heliograph has a range up to 100 m. or more, but is only of really extended use in a country with a large proportion of sunlight.

The very efficient and portable Lucas lamp is a powerful electric lamp with an 8-candle-power bulb set in the back of a cylindrical lampholder with a powerful reflector at its back. An 8-cell battery of ever-ready cells provides a current at an E.M.F. of 12 volts. The lamp has a range in daylight of 2 m. with the naked eye and 3 to 4 m. with the telescope, and at night of 6 m. with the naked eye and twice that distance with the telescope.

The signalling shutter is also a development of the position-warfare phase of the war. It consists of three flaps of American cloth which are black on one side and white on the other. At the back of the shutter are metal clips by which the device can be attached to an ordinary bayonet. The flaps are normally closed with the black side outermost, but by pulling on the operating cord they are pulled down and the white exposed. On releasing the cord the flaps spring back to their original position. When not in use the instrument can be rolled up and stowed in a canvas case.

Message-carrying Agencies.—Of these the most important are (a) despatch riders, mounted orderlies, or runners; (b) carrier pigeons; (c) message-carrying rockets; (d) dogs; (e) air craft.

(a) For use in rear of brigade headquarters the motor cyclist despatch rider is invaluable. A feature of the modern signal service is the organized D.R.L.S. which deals with all official correspondence too urgent for post and not sufficiently urgent for the telegraph. Within brigades, divisions, and in cavalry units and formations, mounted orderlies are often used for conveying messages and this is true of all formations in country impassable to motor cyclists. In the forward battle zone the runner is the last resource of the forward commander. His use should, however, be restricted to occasions when all other means of signalling have failed or are unreliable, for casualties amongst runners are many and men suitable for this duty are not too common.

(b) The pigeon has proved its value for position-warfare conditions during the war. The pigeon service is controlled from corps headquarters and messages from the trenches will usually reach the battalion via brigade or divisional headquarters. The employment of pigeons with tanks and artillery is an important branch of the pigeon service. New developments are their delivery to isolated or front-line posts by aeroplane and parachute, and the teaching of pigeons to fly by night. In the latter case the birds are kept in red light and are flown to a loft where the trap is illuminated by a powerful arc or acetylene light.

(c) Message-carrying rockets with a range of 2,300 yd. have been adopted as a standard means of signalling. Their course through

the air is outlined by a trail of smoke and their position at the end of their flight by a coloured flare automatically lighted at the moment of impact with the ground.

(d) The use of the messenger dog is likely to be confined to position warfare. These dogs have done good service on occasion, but are likely to find their vocation only in stationary warfare or during a very methodical deployment for battle.

(e) In certain phases of a battle the aeroplane is the only trustworthy or even possible intermediary between troops and command. Apart from wireless telegraphy, messages can be communicated to the aeroplane by visual signalling, or if of a simple conventional character, by means of the ground panels used for the notification of positions, while, from the aeroplane to the ground, the most secure method yet discovered is to drop a written message, provided with long streamers, on to selected "dropping grounds" contiguous to the headquarters concerned.

Notification Signals.—Light and smoke signals are made use of as occasion directs and a plentiful supply will be held in store. These are used, under prearranged schemes, for such purposes as calling for barrage or protective fire; notifying positions of forward troops; answering one-way messages, etc. The manufacture of distinctive flares, and light signals generally, has been carried to a very high degree of perfection.

Acoustic signals have not been generally successful with the exception of the Klaxon horn in aircraft. Special sirens and horns for calling attention to gas attacks and other general alarms have been much used, but an attempt made by the French to signal by means of tuned acoustic horns was not very successful. The noises of a modern battle are such as to handicap this method of conveying information very greatly.

(6) **The French Signal Service.**—The French intercommunication service at the outbreak of war differed from the British in being in two separate compartments—a telephone system controlled by the engineers, and a runner and despatch rider service under entirely separate direction. In addition there existed a motor service with the maintenance of liaison between units as its chief duty. The absence of the telegraph in forward formations threw much extra work on the remaining personnel, and caused a consequent increase in the proportion of despatch riders, runners, and orderlies. Construction personnel was in the main kept in the rear and sent forward only when actually required, according to exigencies.

The greatest reliance was placed upon the ringing telephone even in the forward area, and this statement is true even for 1918, although time and again the forward telephone system had been swept away in hopeless ruin by the bombardments which preceded the great position battles. In the rear, the very complete telephone network with an excellent system of locality exchanges served all purposes very well, whether in the normal stationary warfare, in the pressure of traffic before or during an attack from a trench system, or in the hurry of an advance or retreat on a considerable scale. In the last-named case as the attacking armies very soon outran the major portion of their heavy artillery, these well-built lines stood well, and the French system of locality exchanges served the retreating divisions as well as it had served the corps and armies for which it had been originally built.

In the forward area the French signal service was faced with a somewhat different problem from that which confronted the British. Serving a professional staff and a conscript army, far more accustomed to mass manoeuvres than the British armies, a relatively far greater proportion of attention could be paid to getting back information from the front than orders forward to the front. The absence of the telegraph had also taught the forward staffs to rely more upon the spoken word and to dispense to a great extent with those written explanations and confirmations of orders which were considered essential to the British staff procedure.

The British subordinate commander was often able to act upon his own initiative; his French equivalent was not only able but expected to do so to a much greater degree. The result was a far greater use of one-way working, and to this was perhaps due the fact that the power buzzer—essentially a one-way instrument—was first developed in the French army.

A further feature as regards signal policy and practice was a tendency to confine forward routes to front-to-rear routes only. All lateral liaison was by liaison officers, despatch riders, or runners. When a British division was working next the French, the position always involved responsibility for two lateral routes

instead of one.¹ Not only did the French not employ lateral lines, but it was only under suasion that they would make use of them when provided.

The front-to-rear forward routes were mainly of buried cable, though shallow splinter-proof and traffic-proof trenches and narrow open trenches were also employed. "Conic" airline, that is airline built with improvised poles and other stores, which was an invention of the British army, was also adopted by the French, but the latter placed more reliance on fairly heavy routes of poled cable, especially of 7 or 8 cables slung together on pickets 3 to 4 ft. high, a method seldom employed in British divisions except when working in French areas, but which proved very satisfactory when used by a British corps in the advance from the Marne in July 1918.

A further divergence of practice was the concentration upon continuous wave wireless to the exclusion of spark wireless for forward command purposes which was the outstanding characteristic of the forward French wireless service. In 1918, continuous wave wireless was used for command purposes in armies, corps, and divisions and the wireless system achieved a considerable measure of success in the final advances of the autumn. This was the logical outcome of the fact that, on the Allied side, the French were throughout the pioneers of the development of the 3-electrode valve and its application to practical war problems. In no army were the research departments of the signal service keener or better directed. The chief triumph achieved was the designing of such a valve of a much more robust type than any previously produced. This valve, known as the "French" valve, became the standard equipment for the majority of the forward wireless and listening sets both in the French and British armies. (R. E. P.)

(7) *The German Signal Service.*—In the German army before 1914 the signal service formed part of the "Communication Troops" (*Verkehrstruppen*) which had been separated from the engineers for some years. Six Prussian, one Saxon and two Bavarian telegraph battalions existed, and these units, as well as the regimental signal personnel, were trained principally in the buzzer telephone. Wireless telegraphy was provided for by separate detachments, in principle destined for G.H.Q., army headquarters, cavalry formations, and important fortresses. The only other means in use by the signal service of the field army of 1914 was the visual apparatus (*Blinkgerät*), but this was not regarded as having any value in battle, for which the intention was to depend on good tactical and technical handling of the telephones. The strength of the signal service in peace was about 8,500, increased on mobilization to 26,000, and at its maximum in the winter of 1917-8 the establishment reached 102,000. This was nearly an eightfold increase in numbers, but as the number of formations provided with signal units had itself increased, it is more instructive to compare the signal personnel of an army of given strength in 1914 and 1917-8. In the former year, a German army of 12 divisions had about 1,900 signal personnel, and in the latter (nominally) some 9,300. Comparison of these figures with those given above for a British army of 6 divisions in 1914 and in 1918 shows that the German army was at the outset less well-provided than the British, as was indeed to be expected from the long tradition of colonial wars of the latter. At the end of the World War, however, the German signals were, nominally, slightly superior in numbers to the British, though in practice, as the German system assigned to signals certain duties that were not so assigned in the British organization, the strengths—or rather establishments—were about equal for a given force.²

In the first German operations in the western theatre in 1914, intercommunication was in principle by the telephones of the signal service from supreme command to brigade headquarters and by the telephones of the regimental signalling sections (at first, eight men per battalion) farther forward. The flag was also in use, but, as in the British service, it soon disappeared when tested by war. Between the supreme command and armies and cavalry formations, wireless telegraphy—especially in the later stages of the advance to the Marne, when the army telephone detachments failed to keep up with the march—was the principal means of communication and was supplemented by missions of staff officers carried in motor cars. It is admitted by all German critics that this liaison proved far too loose, and its defects are considered to have contributed very largely (some say, principally) to the defeat of the Marne. The for-

ward telephones, on the other hand, in corps signal and in regimental charge, met the demands made on them, to the surprise, it appears, of the army generally, which at the outset had little faith in the utility of technical aids on the battlefield and believed the runner or despatch rider to be the only really trustworthy means of intercommunication. The reconnoitring cavalry was particularly well equipped with telephones, and used a light wire, enamelled to give some degree of insulation to the line in wet weather.

Common to all branches of the intercommunication service was the principle of building from front to rear. Army detachments were responsible for making connexion with the supreme command, corps detachments with army headquarters, and so on. The western campaign of Aug. and Sept. 1914 demonstrated almost at once that this principle was unsound, but only after the penalty for imperfect liaison had been paid.

In the eastern campaigns of 1914-5, and to some extent also in the Rumanian campaign of 1916, conditions imposed upon the Germans radical departures from pre-war regulations. Firstly, the signal units of Hindenburg's armies of 1914 were largely improvised, like many other services and even combatant troops in the East. Secondly, the sparseness of communications and the difficulty of movement compelled the German command from the first to manipulate its signal resources in accordance with the operations in hand or in prospect instead of attempting a schematic layout of lines to all formations alike. Thirdly, the initial mobile warfare conditions continued in the East for more than a year of constant campaigning, and at a later stage, the Rumanian campaign came to prevent the lessons of open warfare from being forgotten. Lastly, the operations began on friendly territory and the policy of the signal service was to build forward from the home telegraph system. These conditions led to (a) enhanced importance of wireless telegraphy, (b) economy of cable, and the use of airline close up to the front, (c) the return to telegraphy for work in rear of corps and even division headquarters, and consequently the development of quick-writing telegraph instruments,³ and (d) the principle of concentrating both wire and wireless communication on a central route connecting a headquarters with a forward report centre (*Meldekopf*, report-head) in the region of the advanced guard, a principle which, for quite different reasons, came into honour later on the western front. The importance of wireless was again emphasized in the Balkan campaign of 1915 and the Rumanian campaign of the following year, in which also the visual apparatus rendered good service.

In the position-warfare campaigns of the West, evolution—speaking very generally—followed the same course on the German side as on the British, similar difficulties and problems naturally suggesting similar remedies. It has already been noted that the numerical growth of the signal service in relation to other arms was approximately the same in the two armies. As regards organization, an important difference was that on the German side the basis of classification was, to the end, the instrument used and not the formation served. Although the signal service branches were combined in one corps of *Nachrichtentruppen* in May 1917, this was subdivided at all echelons into telephone units, wireless units, and visual units. The first-named were responsible for telephones and telegraphs (the latter being largely employed from division headquarters rearward), the wireless detachments for wireless of all kinds and power buzzers, and the visual detachments for the *Blinkgerät*. Moreover, the listening sets, the pigeons and the dogs, were all organized administratively as separate sections of the corps. But in each headquarters, from supreme command to divisions inclusive, the *Nachrichtenkommandeur* was a member of the formation staff and was responsible not only for the command of his own units but also for communication arrangements and procedure generally within the formation, including regimental signallers of infantry, cavalry and artillery, in his capacity as a staff officer. The control and manning of aircraft wireless stations was also in the hands of the signal service, as well as wireless police and wireless intelligence, and (again in his capacity as a staff officer) the divisional signal commander performed many functions that in a British division were assigned to the intelligence officer.

The possibility of applying the recently discovered "audion," or 3-electrode valve, to the purpose of overhearing the opponent's telephone conversations was first realized by the Germans, and the success of this innovation may be said to have revolutionized signal practice on both sides during the war. It made closed metallic circuits in the forward lines and strict telephone discipline essential, and, further, from the listening set there came the "earth telegraph" (power buzzer) which played so important a part in the signalling of all armies in the last two years of the war. But, quite as important as these applications of the 3-electrode valve was its effect on wireless telegraphy through the air. It made possible the change from the spark to the continuous wave system, by providing (a) an intensifier for small, weak receivers such as those of trench and aeroplane sets, and (b) the means of very sharp tuning which allowed of many sets being employed together in a restricted area without mutual interference. Satisfactory trench wireless apparatus on the continuous wave system was designed in 1915 and used in

¹ With British formations amongst themselves the convention was for each to open and to maintain communication with its left-hand neighbour.

² Throughout this comparison, regimental signalling personnel is ignored.

³ The Siemens *Schnellferschreiber* is said to be capable of dealing with 1,000 letters a minute.

the battle of Verdun in April 1916.¹ A further development, made necessary by the adoption of elastic defence tactics in lieu of holding defined trench lines, was the so-called "shellhole" set, which comprised aerial, receiver, transmitter and source of power in a unit weighing only 40 pounds. In elastic defence the visual apparatus also played a useful part.

In trench warfare proper, the Germans did not employ buried cable to the same extent as the British. Their remedy for constant cutting of lines was to put the cables in open trenches sufficiently deep to save them from traffic, and to devote the greater part of the available labour to providing thorough protection for offices, and especially for repair squads. Cable-throwing mortars and messenger dogs carrying reels of self-unwinding cable were occasionally employed to lay lines in conditions of special difficulty. An apparatus known as the "Utel," analogous to the British fullerphone, was evolved to meet the overhearing danger. The visual *Blinkgerat*, message-carrying projectiles and rockets, and especially pigeons, were used to supplement the telephone and the wireless communications, as in the armies of the Entente. Unexpectedly good results were obtained with messenger dogs, powerful and intelligent wolflike animals, specially trained and carefully bred.

For the great offensive battle of March 21 1918, the experiences both of the eastern and the western fronts were drawn upon. Between army and corps headquarters, and also between corps and division, the principle of the central route with a *Meldekopf*, to which all forward units made their connexion, was adopted. For the forward units special arrangements were made for transport and routes over the shellhole area. The wireless units were reorganized to permit of great subdivision, and the divisional wireless troop was equipped with its own transport. Visual apparatus was similarly made mobile and self-supporting, and a system of light, smoke, and other recognition signals completed the preparation for battle. In spite of losses and friction telephonic communication was successfully kept up as far forward as regimental headquarters during the first days of the offensive. Thereafter, however, the telephone system broke down owing to the inability of the sections to maintain their lines against the enemy's shell fire and even more the ceaseless movement of transport in the ever-deepening battle zone. Pigeons, even, could finally only be got to the front units by means of aeroplanes. Earth telegraphy failed for want of range; message-carrying projectiles and dogs for the same reason were only occasionally useful, and in the later rapid stages of the advance intercommunication from front to rear depended almost entirely upon wireless telegraphy and upon simple notification signals (such as panels shown to aircraft, light and smoke signals of agreed meaning) in the hands of the troops themselves. The wireless system was based on the divisional central route, which was maintained by two powerful units, each alternately keeping up communication between *Meldekopf* and headquarters and moving forward to a new, more advanced *Meldekopf*. The small wireless sets distributed in the front zone, the other reporting agencies, and the staffs, made their connexion with the head of this extending route wherever it happened to be at any moment, while the telephone units, largely reinforced by fresh units hitherto reserved at the disposal of the supreme command and aided by captured material, followed on with airline. This system served its purpose, and the efforts of the signal service were rewarded by special mention in the *communiqué* of March 26, but normal signal traffic did not become possible again till the advance had slowed down sufficiently to enable the telephone units to catch it up.

In their rearward signal communications, the Germans made much use of Pupin coils to bring their iron wire (adopted from motives of economy) up to the technical efficiency of copper wire, and also to increase the efficiency of the latter for long distance telephony. Direct telephonic communication between the German and the Turkish supreme commands was opened in 1917. The use of quick-writing telegraph instruments has already been alluded to.

(C. F. A.)

(8) *United States Army*.—In the United States army, the signal corps has been a separate organization for many years. The units into which it was organized in 1917-8, apart from those serving in the "S.O.S." or lines of communication in France, were of two main classes, field signal battalions and telegraph battalions. To an army were assigned two telegraph battalions and one field signal battalion; to each corps were assigned one telegraph battalion and one field signal battalion; and to each division, one field signal battalion. The telegraph battalions consisted of two companies each, while the field signal battalions each consisted of three companies, a wire company, a radio company, and an outpost company, the latter battalions including 470 men. The outpost company was responsible for commu-

nication at and in advance of infantry brigade headquarters working in four regimental sections in position warfare and in two brigade sections in mobile warfare. The radio company was equipped for all types of radio communication within the divisional area. The wire company constructed and operated the normal system of communications between the division headquarters and the artillery headquarters between the former and infantry regimental headquarters. The corps and army signal units were responsible for maintaining and operating lines forward to the next subordinate headquarters and to certain troops of their own respective headquarters.²

A distinct feature of the work of the United States army signal corps was the tendency for the preponderate use of the telephone over the telegraph and the very full and wide provision of telephone facilities. This characteristic is due to the fact that in the United States, the telephone organization is highly developed and the "telephone habit" wide-spread amongst all classes. Hence there would be a wider demand for such facilities, a greater familiarity in operating under circumstances of heavy traffic, and a greater manufacturing capacity for producing telephone equipment, than in the case of other countries.

The signal corps also included the meteorological, the pigeon and the radio direction-finding service and, until late in the war, the aviation service of the United States army.

SILESIA, UPPER.—It was provided in 1919 by the Peace of Versailles (Art. 88) that the inhabitants of Upper Silesia (pop. in 1910, 2,280,902) should be called upon to decide by a plebiscite whether they would belong to Germany or Poland (*see* PEACE CONFERENCE). It should be noted that for the purpose of the plebiscite the purely German districts of Falkenberg (pop. 37,526), Grotthau (pop. 40,610), Neisse (pop. 7,781), part of Neustadt (pop. 25,000) and Hultschin (pop. 45,552), situated in the northern and western parts of Upper Silesia and representing a total population of about 156,469, were excluded. Up to the day of the plebiscite the supreme authority in the plebiscitary area was to be vested in an Inter-Allied Commission, consisting of one representative of France, Great Britain and Italy respectively. In this commission France was represented by Gen. Lerond, England by Col. Percival, and Italy by Gen. de Marini. On Feb. 1 1920 Allied troops occupied the plebiscitary district. The local German officials were then subordinated to the Inter-Allied authorities. The German police (*Sicherheitspolizei*) was replaced by a special polling police (*Abstimmungspolizei*), which was composed half of German-speaking, half of Polish-speaking, Upper Silesians.

On the whole the collaboration of the Inter-Allied control and the German officials proved satisfactory; but various differences arose, such as that which led to a strike of judges in May 1920. Both the Poles (under Korfanty) and the Germans opened an active canvassing campaign; and under Polish pressure the Germans in the southern and eastern districts were subjected to oppressive treatment. On Aug. 19 1920 the Poles felt strong enough, indeed, to make an attempt to seize the country by force. On all sides bands of Poles, chiefly recruited from Congress Poland, usurped authority. A number of Germans were forcibly carried across the frontier into Poland, and many were killed. Several weeks elapsed before it was possible to quell this rising and restore order. In the autumn of 1920 there was an exchange of notes between Germany and the Entente relating to the manner in which the plebiscite should be taken. It had been suggested by the Entente that the non-resident Upper Silesians of the German Reich should vote outside Upper Silesia, at Cologne. Germany protested against this, and her protest was recognized as valid by the Entente. In Jan. 1921 the date of the plebiscite was fixed for March 20 1921. An immediate revival took place in the use of terrorism by the Poles, especially in the districts of Rybnik, Pless, Kattowitz and Beuthen. It reached its climax in the days preceding the plebiscite. Voters from other parts of the German Reich were frequently refused admission to

¹ The experiment was very successful, but the higher authorities for some time refused to allow the general adoption of trench wire-
less on the ground that it involved a reduction of infantry strength.
² But a stronger motive was no doubt the fear of interception.

² In comparing the strength of these organizations with those of other armies, it must be remembered that the United States army division was much stronger than the corresponding unit of other armies. It comprised two infantry brigades each of two 3-battalion regiments and one artillery brigade of two field and one medium artillery regiments besides other divisional troops.

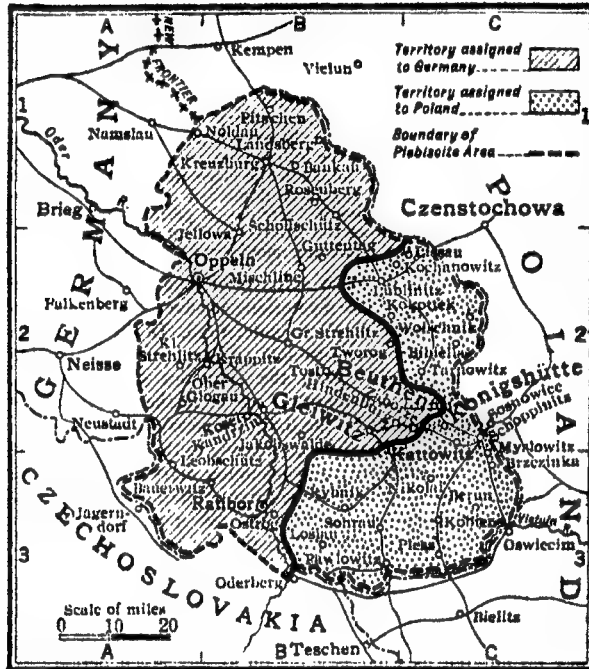

the polls; sometimes they were maltreated and even in some instances murdered; and houses where outvoters were staying were set on fire. The day of the plebiscite passed, however, without disturbance except at a few places, such as Rybnik and Pless.

The day after the plebiscite the Polish excesses recommenced, and from that date onwards continued without interruption; nor was the Inter-Allied Commission able as a rule to prevent them. The poll showed 717,122 votes for Germany and 483,514 for Poland. In 664 districts there was a German, in 507 a Polish majority. Practically all the towns voted for Germany. There was a Polish majority in the following administrative districts—Rybnik, Pless, Beuthen, Tarnowitz and Gross-Strehlitz. The decision of the Inter-Allied Commission as to the allocation of the disputed regions to Germany or to Poland was delayed on account of differences which arose within the commission itself; the French representative, Lerond, who had from the first been accused of tacitly supporting the Poles, wished to allot the whole of southern and eastern Upper Silesia to them, while the English and Italian representatives wished to apportion the industrial region to Germany. Protracted diplomatic negotiations between Paris, London and Rome did not lead to any result. At the end of April a report became current that the Council of Ambassadors at Paris had determined to give only the districts of Rybnik and Pless to Poland. In consequence of this rumour the first days of May witnessed a new Polish insurrection which assumed far greater proportions than the former one. Korfanty had secretly raised a well-organized Polish force which was provided with arms and munition from across the frontier, and was reinforced by large bodies of men from Poland. With these troops he occupied the whole south-eastern part of Upper Silesia, on a line extending from the S. of the district of Kreuzburg through Gross-Strehlitz to the Oder in the south. He nominated himself dictator of the districts under Polish occupation, took over the administration, and treated even the Allied officials with such scant consideration that they were obliged to withdraw to Oppeln and the regions that were not occupied by the Poles. It was only in the larger towns, where there was a German majority, that the Allied troops, supported by the German population were able to maintain themselves. A further advance on the part of the Poles was prevented by the German Defence Force (*Selbstschutz*) under Gen. Höfer, which was composed of Upper Silesians and Germans who poured in from other parts of the Reich. There was severe fighting between the German Defence Force and the Poles, especially in the districts of Ratibor and Gross-Strehlitz. Colonel Percival, the British representative, was obliged to resign owing to ill-health, and was succeeded by Sir Harold Stuart. Attempts on the part of the Inter-Allied Commission to put an end to the insurrection by negotiations with Korfanty were unsuccessful, and the Allies were compelled to despatch reinforcements of French and British troops, under the command of Gen. Heneker, to Upper Silesia. After lengthy negotiations with the German Defence Force, which refused to withdraw unless guarantees were secured that the Poles would first quit the field, an agreement was ultimately effected with regard to the evacuation. By June 20 the British troops had again occupied the larger towns, while the Poles had the upper hand in the rural districts. As a result of the difficulties in paying his men and providing them with food Korfanty now lost control over his followers. Independent bands were formed which plundered the villages, ill-treated the Germans, and murdered many of them. In the industrial districts work in many of the mines and iron works came to a standstill, because imports of raw material and exports of coal had become impossible. By the end of June the loss suffered by the industrial region was estimated at 3 milliard marks; and there seemed to be no prospect of the restoration of tranquillity.

The French adhered to their contention that the greater part of the industrial region should be assigned to Poland. Great Britain, on the other hand, firmly maintained the view that such a partition would, as Mr. Lloyd George publicly expressed it, be "unfair" to Germany on the basis of the Treaty of Versailles and the result of the plebiscite. There were at one time three

rival proposals for partition: (a) the Korfanty line, the extreme Polish demand; (b) the Sforza line, a proposal put forward by the then Italian Foreign Minister, (c) and the British proposal giving Poland only the south-eastern corner with the towns and districts of Pless and Rybnik. France was ultimately left in a minority of one on the Supreme Council, Italy and Japan having adhered to the British view. After prolonged debates and open differences among the principal Allied Powers on the subject of the partition, it was at last arranged, at a Paris conference in Aug. 1921, that the solution should be entrusted to a Commission of the Council of the League of Nations. This commission was ultimately constituted by the representatives of Japan, Brazil, China, Spain and Belgium, with the Japanese representative, Baron Iishi, as chairman. (C. K.*)

On Oct. 20 1921, the text was published of the documents containing the award of the League of Nations on the partition

Upper Silesia Frontier, 1921

of Upper Silesia. The proposed new frontier line between Germany and Poland was as shown by the appended Map. The division here made in the industrial area, previously German, was such that the Council of the League of Nations declared it to be desirable, however, that measures should be taken to guarantee the continuity of the economic life of the region during a provisional period of readjustment, and to provide for the protection of minorities. It was recommended, therefore, that a general convention for this purpose should be concluded between Germany and Poland, so as to place Upper Silesia under a special regime during the transitional period, and that an "Upper Silesian Mixed Commission" should be set up as an advisory body, composed of an equal number of Germans and Poles, with a president of some other nationality to be designated by the Council of the League, together with an arbitral tribunal for settling private disputes occasioned by the temporary measures.

The provisional or transitional period was to be 15 years, and certain stipulations were laid down by the League of Nations for the economic arrangements during that period in the "plebiscite area." (1) Railway and tramway systems, privately owned or municipal, were to continue under the terms of their concessions, and the German State railways were to be put under a joint system of operation. Railway rates were to be uniform. The State insurance of employees in the Silesian railway system was to be undertaken by that system. A single Accounts Office was to be set up for the whole system. Expenses of new construction to be charged to a separate account, and borne by the State in whose territory it was carried out; the working capital for operation to be

lent by the German State, and interest charged to the account of this system; profits or deficits to be divided between the two countries in proportion to the length of line and amount of traffic belonging to each. (2) The German mark was to be the only legal unit of currency, and Poland was to recognize the rights of the Reichsbank, for a period not exceeding 15 years, but by agreement the two Governments might modify this arrangement earlier. (3) While the German monetary system was maintained in the Polish zone, the postal telegraph and telephone charges should be in German currency. (4) The customs frontier would coincide with the political frontier, and the German and Polish customs law would apply, with certain exceptions. For 6 months, incoming goods from other countries, on which German or Polish duties had been paid previously to the partition, should cross the frontier without duty. For 15 years, natural products originating or coming from one of the two zones of the plebiscite area and destined for consumption in the other should cross the frontier free of duty. For six months, raw, half-manufactured and unfinished products of industrial establishments in one zone, destined for industrial establishments in the other, should cross free of duty; and this should continue for 15 years when the products, as finished, were intended for free importation into the country of origin. Natural or manufactured products originating in the Polish zone should, on importation into the German customs territory, be exempt from duty for three years from the date of the frontier-delineation. As regards export, the two countries should facilitate for 15 years the export of such products as were indispensable for industry in either zone. (5) Poland was to permit, for 15 years, the exportation to Germany of the products of the coal mines in the Polish zone, and Germany similarly to Poland in respect of the mines in the German zone. (6) For the 15 years, any inhabitant regularly domiciled or occupied in the plebiscite area should receive a "circulation permit" free of payment, enabling him to cross the frontier without other formalities. (7) Generally, the two countries should respect private rights.

SILVER (see 25.112).—Few subjects of economic importance present such a phase of the mysterious as silver, and the reason for this is perhaps not difficult to understand. In the case of the world's crops, not only are up-to-date and approximately reliable statistics daily available from the countries of production, but the countries of consumption see to it that they equally are in the foreground as to the daily progress of world's crops; and the manner in which statistics relating to these all-important subjects are now presented to consuming markets has become quite an art. For some reason the same attention unfortunately has not hitherto been—and is not even now—paid to the production of silver. Most excellent statistics are presented annually by the U.S. Director of the Mint, by the Government of India, and in pre-war days by the German *Metallgesellschaft*, but these unfortunately are what we may term "post date" figures, and, whilst of great value in informing the student as to what has been, they do not tell us what is going on at any given period.

This state of affairs is no doubt due to the great difficulty which has always been experienced in obtaining definite and conclusive data as to the production of silver, owing to the fact that the metal is now chiefly obtained as a by-product and not from mines worked solely for silver itself. Generally speaking the most important metals with which silver is associated are—gold, copper, lead and zinc. Gold and silver invariably occur together. Lead and zinc usually accompany one another, and the ores carrying these two metals—particularly where lead predominates—are frequently fairly rich in silver. Lead and silver usually form an especially marked combination, whilst copper is frequently associated with both gold and silver. These ores are generally described as silver lead, silver lead zinc, silver zinc and gold silver ores, and the mines producing these ores are not uncommonly spoken of as silver mines, overlooking the fact that the ores of the base metal have to be treated by smelting methods before the silver can be extracted. The quantity obtained in these ores ranges from about 2 to 50 oz. to the ton.

The production of silver, therefore, may now be said to be dependent upon that of gold, copper, lead and zinc; and consequently any causes which affect the production of these metals largely affects the production of silver as a by-product, and the world's demands for these metals will in a great measure control the future supplies of silver. Estimates from what are considered good sources give the percentage of the world's production of silver as ranging from 70% from base metal ores and 30% from precious metal ores.

Table 1.—World's Production, 1860-1919.

Year	Fine oz.	Year	Fine oz.
1860	29,095,428	1890	126,095,062
1861	35,401,972	1891	137,170,000

1880	74,795,273	1910	221,715,763
1881	79,020,872	1911	226,192,923
1882	86,472,091	1912	224,310,654
1883	89,175,023	1913	223,907,845
1884	81,567,801	1914	168,452,942
1885	91,609,959	1915	184,204,745
1886	93,297,290	1916	168,843,000
1887	96,123,586	1917	174,187,800
1888	108,827,606	1918	198,168,408
1889	120,213,611	1919	174,517,414

In order that an idea may readily be obtained of the centres from which production is now derived, the figures in Table 2, from the annual report of the U.S. Director of the Mint (1920), supplement those given in Table 1 for production itself.

Table 2.—Production of silver (10,000 oz.) by countries.

	1914	1915	1916	1917	1918	1919
United States	7,246	7,500	7,441	7,174	6,781	5,668
Canada	2,840	2,660	2,546	2,222	2,128	1,568

	16,843	18,412	16,882	17,416	19,738	17,451

United States.—The production of silver in the United States, the bulk of which comes from the western states, has always constituted a high proportion of the world's supply. Generally speaking the major portion of U.S. silver is obtained from gold, copper, lead and zinc ores mined in the States and metallurgically treated in that country. In addition large quantities of similar ores are imported from other countries—Mexico, Central America, Peru, Bolivia, Chile and Canada—for treatment, and the silver thus resulting goes to swell the U.S. figures of production of refined silver. The United States first came into prominence as a large producer in 1859 when operations on the famous Comstock lode in Nevada began. In 1860 the production was 116,019 oz., and in 1915 the output reached the high figures of 74,961,075 ounces. The preliminary official estimate of the production in 1920 was 56,564,504 oz., a reduction of 117,941 oz., as compared with that of the preceding year.

On April 23 1918 the Pittman Act became law in America, under which it is provided that: "The Secretary of the Treasury is hereby authorized from time to time to melt or break up and sell as bullion not in excess of \$350,000,000, standard silver dollars now or hereafter held in the Treasury of the United States." This \$350,000,000 represented about 270 mill. fine oz., of which the share of India was reported to have been 200 mill. fine oz., all of which was received in India between July 1 1918 and July 17 1919. The Act also provided that these sales were to be replaced by purchases of silver actually mined in the United States at the rate of \$1. per oz. pure. The total purchases by the U.S. Treasury under this Act up to May 17 1921 totalled 54,120,197 oz., thus leaving 145,879,803 oz., still to be repurchased.

Mexico.—This country can safely be described as first among silver-producing countries of the world, in spite of the decreased output of recent years following upon the outbreak of civil war in 1913. The silver-bearing ores are widely distributed throughout the country; the mines and mining districts are exceedingly numerous, and many of the mines have been in continuous operation for hundreds of years. In 1911 the mine production of silver was reported as 79,032,440 oz.; in 1914, owing to the civil war, it dropped to 27,546,752

oz., but subsequently the output steadily increased up to 1920. As to what the future Mexican production would be time alone could prove, but in 1921 good authorities did not hesitate to predict that, given a recognized and stable Government and a reasonable price, it would later exceed that of Mexico's palmiest days.

Canada.—The Canadian production of silver hitherto has occupied the third position in the world's list of supplies. The metal is found chiefly in Ontario, British Columbia, Quebec and Yukon. The Ontario silver has been almost entirely derived from the silver ores of Cobalt, which field, however—judged from a continually reduced output—would appear to be working out. The British Columbia, Quebec and Yukon supplies are derived mainly from silver, lead and copper ores. In 1920 reports were coming to hand of discoveries of further silver-bearing ores which promise important results. In 1900 the total Canadian production was given as 4,468,225 fine oz., of which 3,958,175 came from British Columbia; in 1910 the Canadian output had increased to 32,869,264 fine oz., of which Ontario accounted for 30,366,366, whilst in 1919 the output was reduced to 15,675,134 fine oz., and the 1921 production seemed likely to show a further reduction.

Central American States.—The silver produced in these States—mainly Honduras, Costa Rica and Panama—is chiefly derived from gold-silver ores; the production in 1914 amounted to 2,754,868 fine oz., and in 1919, according to figures supplied by the director of the Washington mint, to 2,800,000 fine ounces.

South American States.—The countries included under this category rank as fourth producers of the metal. In early days the true silver mines in Peru, Chile and Bolivia ranked amongst the most important in the world, but as in the case of the older mines of Mexico they appear to be no longer in operation, and the production is being chiefly derived from base metal ores—copper and tin. In 1917 the production of Peru was reported as 10,865,061 oz., and in 1919 as 9,781,734 ounces. Bolivia in 1902, according to the U.S. mint reports, gave 12,992,641 fine oz., whilst in 1919 the production had dropped to 2,435,000 fine ounces. Chile was reported to have reached 2,349,379 fine oz. in 1900 and 1,900,000 fine oz. in 1919.

Europe.—Prior to the World War Germany was looked upon as the largest producer in Europe, and according to the *Metalgesellschaft* reports, the silver which is chiefly derived from base metal ores reached a production in 1904 of 5,822,727 fine ounces. The major portion of the concentrates from which the silver was extracted came from the Broken Hill mines in Australia.

Spain.—Next in Europe to Germany as a producer comes Spain, whose output of silver is mainly obtained from her important lead and copper ores. In 1915 her output was given as 4,565,396 fine oz., whilst in 1919, according to U.S. mint reports, it was stated to be 2,900,000 fine oz.—probably an approximate estimate.

United Kingdom.—It is impossible to say what the refinery output of silver in Great Britain is. It may, however, be stated that it is practically all obtained from imported ores treated in the country. The proportion of domestic mined ores is far too small for consideration. The number of refiners engaged in this business is considerable, but as they never publish returns, the difficulties experienced in arriving at anything approaching a reliable figure will be appreciated. According to the "Census of Production" the total output in the United Kingdom in 1907 was given as about 43,979,000 oz., troy.

Australia.—New South Wales stands preëminent as the chief Australian producer, the silver being mainly obtained from the wealthy silver lead ores treated at the Broken Hill Works at Port Pirie. Their output for 1919 has been given as 6,304,818 fine ounces.

Africa.—The Transvaal, Cape Colony, and Natal provide the main output, and the 1919 production has been stated to be 891,304 fine oz., at the same time a not inconsiderable proportion of their gold-silver ores are shipped to and refined in England.

Asia.—The chief countries producing silver are Japan and India. The production of copper has made great strides in Japan of late years, and it is chiefly from these ores that her silver is obtained; the metal is also obtained from the gold ores mined in Formosa and Korea. Japan's output of silver in 1917 was reported at 6,844,500 fine ounces.

The Indian output is chiefly derived from the mines in Upper Burma belonging to the Burma Corp. Ltd., and the production from Jan. to Oct. 1920 amounted to as much as 2,014,261 oz., and it was said that 1,000,000 oz., per month would in the future be a very possible output. What India ultimately would be able to produce must remain problematical, but there is no question whatever about India's potential mineral wealth, which only requires time to develop.

Consumption of Silver.—Although great difficulties are experienced in obtaining definite data as to production, that problem is relatively simple in comparison with the consumption side of the subject. Briefly stated, consumption may be discussed from four standpoints—the respective world nations' coinages, their arts, and the requirements of India and China, and it is here that the absence of readily obtainable and reliable information is felt. In the case of America the admirable figures annually presented by the U.S. director of the mint, in so far as America is concerned, supply the following information:—

American silver coinage.

1918	35,004,450 fine oz.
1919	14,682,079 " "
1920	19,763,600 " "

Industrial arts.

Silver consumed	Of which new material
1917 27,039,845 fine oz.	15,998,807 fine oz.
1918 36,252,596 " "	26,722,333 " "
1919 32,700,521 " "	26,237,519 " "

As regards the coinage requirements of other nations, a most remarkable reversal of conditions has arisen. Prior to the World War the annual requirements for such purposes probably amounted to 70,000,000 oz. at least. In 1921 that was all changed, and the spectacle was presented of a great number of countries demonetizing silver as quickly as possible, and / or reducing the fineness of their silver coinages. England had reduced hers from 925 to 500, and the Straits Settlements from 900 to 500. The quantity of silver which had already been placed on the market, though somewhat problematical, was probably 50,000,000 oz., with a fairly safe estimate of as much more to follow.

As regards the world's requirements for arts, it may be safe to say that the majority of European countries were in 1921 in far too impecunious a position owing to the war to become real factors under this heading for many years to come—in fact, the majority had been and still were sellers of silver ware.

Table 3.—Silver coin and bullion imported into and exported from British India, 1887-1919. (British standard ounces.)

Fiscal yr. ended March 31.	Imported	Exported	Net Imports
1887-8	37,877,141	5,994,542	32,782,599

In studying the figures for British India (Table 3) very great care is necessary to discriminate between what represents Government and what private imports, as the Government figures are for coinage purposes entirely. The need for this will be apparent when it is realized that out of the figures given in Table 3 for the years 1912 to 1919 Government coinage requirements were:—

	Standard oz.
1912-3	56,057,978
1913-4	35,425,057
1914-5	169,342
1915-6	302,259
1916-7	109,522,499
1917-8	79,404,555
1918-9	237,189,080

As the stock of silver held by the Government of India in their currency reserve, according to the return dated May 22 1921,

amounted to Rs. 66,41,00,000—against an average for the five pre-war years, 1910-4, of Rs. 21,99,00,000—it may safely be assumed that they were not likely to be purchasers of the metal for some years to come.

As regards China's consumption, it is an almost hopeless task to supply anything approaching reliable data. The figures in Table 4, however, taken from the Chinese Maritime Customs reports may be taken as approximately correct—they are, however, given in Haikwan taels.

Table 4.—China.

	Imports	Exports
1914	861,167 taels	13,861,917 taels
1915	818,827 "	18,211,040 "
1916	19,903,117 "	8,102,268 "
1917	13,871,778 "	5,024,575 "
1918	1,228,342 "	2,281,059 "
1919	51,078,643 "	9,896,429 "
1920	50,966,880 "	68,460,360 "

Imports into Hong Kong for the year 1920 were reported to be the equivalent of £7,040,700—the greater portion of which was probably dealt with by the mint in Canton. The stocks of silver held in Shanghai on Dec. 31 of the following years are shown in Table 5. The increase in stocks in 1920 over 1919—viz, taels 15,460,000, and dollars 18,420,000—represents the equivalent of an increase of about 31,030,820 ounces.

Table 5.—Stock at Shanghai.

	Taels	Dollars	Bar Silver
1917	21,700,000	14,640,000	357
1918	18,860,000	13,470,000	4
1919	19,140,000	11,260,000	242
1920	34,600,000	29,680,000	nil

Prices.—Table 6 gives the highest, lowest and average price of bar silver in London per oz., British standard—925 fine—since 1833, from which it will be seen that the highest quotation recorded since 1833 was 89½d. in 1920, the next highest being 79½d. in 1919, 62½d. in 1859 and 62½d. in 1864. Though the highest point reached was in 1920, the average quotation for that year was only 61½d. against averages in 1850 of 62½d. and 61½d. in 1864, which would point to more stable conditions existing in the silver market in the years 1850 and 1864 than in 1920. To the years 1902 and 1903 belong the honour of recording the lowest prices, viz. 21½d., whilst the lowest average goes to 1915 with 23½d. followed by 1909 with 23½d. When the Pittman Act became law in the United States, good authorities, not only in America but in England, made bold to assert that the result of this Act would be to stabilize the world's price of silver at not less than \$1 per oz., for many years to come, whilst Senator Pittman went further and predicted that the world's price would range between \$1—and \$1.29—the parity of the American silver dollar—for the next 20 years. The spot price in London on June 1 1921, was 33½d., and the price in America on the same date for foreign mined silver was 60 cents nominal.

Table 6.—Highest, lowest, and average price of bar silver in London, per oz. (British standard 0.925) from 1833 to 1920.

(W. E. P.)

SIMON, SIR JOHN ALLSEBROOK (1873—), British politician and lawyer, the son of a Congregational minister, was educated at Fettes, and at Wadham College, Oxford, where he was a scholar and was eventually elected an hon. fellow. He became pres. of the Union in 1896, and took a first-class in *Lit. Hum.* in the same year, being subsequently elected fellow of All Souls. He went to the bar, became Barstow Law scholar in 1898, and was called in 1899. His manifest abilities and the persuasiveness of his advocacy soon brought him into notice; he was chosen one of the counsel for the British Government in the

arbitration on the Alaska Boundary in 1903; and he rapidly attained so considerable a practice that he was able to take silk in 1908. Meanwhile he had gone into politics, and was elected as an advanced Liberal for Walthamstow at the general election of 1906. At first, probably owing to his absorption in his legal work, he did not command nearly so much attention in Parliament as his Wadham contemporary and fellow-lawyer, Mr. F. E. Smith (afterwards Lord Birkenhead). But he gradually made his way, and was appointed by Mr. Asquith solicitor-general in 1910, and Attorney-General with a seat in the Cabinet in 1913. On the outbreak of war in 1914, his resignation, along with those of Lord Morley and Mr. Burns, was confidently expected; but he finally decided to remain with his chief and the bulk of his colleagues. When the first war Coalition Government was formed in May 1915, he was offered the lord chancellorship, but he declined the greatest prize of his profession as he preferred a political career in the Commons. Accordingly he accepted the home secretaryship, and gave up his legal practice, by means of which he had acquired a comfortable fortune. Early, however, in the following year, owing to his inability to accept the Government bill for compulsory military service, he resigned his office and led a fruitless opposition to the measure in the House; and then went out to the front in France as a major in the R.A.F. He subsequently resumed practice as a barrister, and immediately regained his position in the front rank of his profession. On the break between Mr. Asquith and Mr. Lloyd George, Sir John Simon adhered to the former. He lost his seat in Parliament at the general election in Dec. 1918, subsequently taking an active part in political work outside the House in the interests of the Independent Liberals. He was twice married—in 1899 to Ethel M. Venables, who died in 1902, leaving a son and two daughters, and in 1917 to Kathleen Manning.

SIMS, WILLIAM SOWDEN (1858—), American naval officer, was born at Port Hope, Ont., Canada, Oct. 15 1858. In childhood he removed to Pennsylvania and was graduated from the U.S. Naval Academy in 1880. Then for eight years he served on board various ships in the N. Atlantic. During 1880-93 he was with the nautical school ship "Saratoga," and then was transferred to the Pacific Station, and later to the China Station. From 1897 to 1900 he was naval attaché to the American embassy, first at Paris and afterwards at St. Petersburg. In 1900 he returned to the Pacific Station. Convinced of the inadequacy of American methods of target practice Lieutenant Sims wrote numerous letters to the Washington officials urging changes. Meeting with no response he finally addressed a personal letter to President Roosevelt, which led to his recall to Washington. In the end he was enabled to arrange for a gunnery test and proved his claims. In 1902 he was assigned to the Bureau of Navigation, serving for the next seven years as inspector of target practice, which was remarkably improved under his guidance. Meanwhile in 1907 he was made commander and appointed naval aide to President Roosevelt. With this rank he was placed in charge of the battleship "Minnesota" in 1909. The following year, during a visit of the Atlantic Fleet to England, Commander Sims caused a stir by certain indiscreet remarks made at a dinner at the Guildhall, London, where he said: "Speaking for myself, I believe that if the time ever comes when the British Empire is menaced by an external enemy, you may count upon every man, every drop of blood, every ship, and every dollar of your kindred across the sea." A semi-official protest against this utterance was made at Washington by the German Government, which took offence at it, and there was some talk of Sims being dismissed from the service, but the incident ended in a severe reprimand from the Secretary of the Navy. In 1911 he was promoted captain and for two years was a member of the staff of the Naval War College, Newport, R.I. During 1913-5 he was in command of the Atlantic Torpedo Flotilla and then returned to Newport as president of the Naval War College. When America entered the World War in April 1917 he was chosen to command American naval operations in Europe. In Jan. he had been promoted

rear-admiral, and early in April, when war was imminent but before its formal declaration, he sailed in disguise to England in a merchant vessel. In May he was made vice-admiral. In 1916 he had urged construction of battle cruisers, arguing their supremacy over submarines as shown in the battle of Jutland. In his book *The Victory at Sea* (1920, in conjunction with Burton J. Hendrick) he shows how the convoy system, used in transporting 2,000,000 American troops, frustrated the submarines. In 1919 he criticised the manner in which naval honours had been awarded; in particular, he held that "the commanding officer of a vessel that is sunk by a submarine should not receive the same reward as the commanding officer of a vessel which sinks a submarine." This criticism was obviously directed against the Secretary of the Navy for having decorated his own son-in-law, whose boat was sunk. He himself refused the D.S.M. In 1920 he made a formal report to the U.S. Senate, and charged the U.S. Naval Board with serious errors in the conduct of naval operations during the war. His English sympathies and his admiration for the British navy were openly expressed—too openly for the liking of some of his critics.

SINCLAIR, MAY (—), English author, was born at Rock Ferry, Cheshire, and educated at the Ladies' College, Cheltenham. She began her career by writing verse and philosophical criticism. In 1895 she published her first short story, followed in 1896 by her first novel *Audrey Craven*. *Mr. and Mrs. Neville Tyson* appeared in 1898 and *Two Sides of a Question* in 1900. But it was not until she published *The Divine Fire* in 1904 that she became widely known. It was followed by *The Helpmate* (1907); *Kitty Tailleur* (1908); *The Creators* (1910); *The Combined Muse* (1913); *The Three Sisters* (1914); *Tasker Jevons* (1916); *The Tree of Heaven* (1917); *Mary Olivier* (1919) and *The Romantic* (1920), as well as one or two volumes of short stories. In *A Defence of Idealism* (1917) Miss Sinclair published acute criticisms of modern philosophic theories, and in a *Journal of Impressions in Belgium* (1915) she gave her experiences in the autumn of 1914 as a member of an advance field ambulance.

SINHA, SATYENDRA PRASSANO, 1ST BARON (1864—), Indian statesman, was born of an ancient Kayastha family in the village of Raipur, Birbhum district, Bengal, in June 1864. Matriculating at 14 he held a scholarship at the Presidency College, Calcutta, and in 1881 came to London to join Lincoln's Inn, where he won many prizes and scholarships, and was called to the bar in June 1886. In practice at Calcutta he rapidly rose to a leading position, and was appointed standing counsel to the Government of India in 1903. He was the first Indian to be appointed advocate-general of Bengal (1908), and the first to become a member of the Government of India. He held the law portfolio from April 1909 to Nov. 1910, up to the retirement from the viceroyalty of Lord Minto, who testified to the success of what some English critics regarded as a dangerous experiment. Sinha resumed his lucrative practice at the bar, presided at the Indian National Congress session at Bombay in 1915, and was again appointed advocate-general of Bengal (1916). He and the Maharaja of Bikaner were the first Indians to participate in Empire deliberations in London, for in 1917 they jointly assisted the Secretary of State at the meetings of the Imperial War Cabinet, and were members of the Imperial War Conference. Sinha joined the Bengal Executive Council in the same year, but returned to England in 1918 as a member of the Imperial War Cabinet and Imperial War Conference. Immediately on getting back to India he was called to London and Paris as an Indian member of the Peace Conference. Knighted in 1915, in 1918 he was made K.C., a distinction not previously conferred upon a barrister of Indian birth or practice. When the Coalition Government was recast at the beginning of 1919 he established further records for an Indian by being appointed to the Ministry as Under-Secretary for India, and being raised to the peerage as Baron Sinha of Raipur. He was the second Indian to be sworn of the Privy Council. He skilfully conducted the Government of India Act, 1919, through the House of Lords, and when dyarchy was initiated at the close of 1920 was appointed governor of Bihar and Orissa, being the first Indian to preside over a British province.

SINN FEIN: see IRELAND: *Political History*.

SKEAT, WALTER WILLIAM (1835-1912), English author (see 25.168), died at Cambridge Oct. 6 1912.

SLATIN, SIR RUDOLF CARL VON (1857-), Anglo-Austrian soldier and administrator in the Sudan (see 25.212). For his capable and gallant services in the Sudan Slatin Pasha had been created K.C.M.G. and had received the thanks of both Houses of Parliament in 1899. In 1906 he was created a baron of the Austrian Empire and was made an Austrian privy councillor in 1904. The same year he married Baroness Alice von Ramberg of Vienna (d. 1921). In 1912 he received the G.C.V.O. from H.M. King George V. On the outbreak of the World War, Slatin, who was on leave in Vienna, was prevented, by the Austrian mobilization, from returning to his appointment in the Sudan, and in this difficult position he voluntarily took up work as head of the Austrian Red Cross, and in charge of prisoners-of-war, and would accept no remuneration for his services. In this capacity he did much to ameliorate the conditions of imprisonment, and was largely responsible for the humane treatment of the Allied soldiers in Austrian hands. The German Government (through Bethmann Hollweg) offered him a high post which he refused. Subsequent to the signing of the Armistice, he was selected as a member of the Austrian delegation to discuss the terms of peace in Paris.

SMILLIE, ROBERT (1859-), British labour politician, was born in Belfast in 1859 of Scottish parents. He was sent to a primary school but left at the age of 14 years to work in a shipyard at Govan. Two years later he went into the mining industry of Lanarkshire and worked underground for 16 years. From 1878 onwards he was an active trade unionist, although in the earlier years of this period he was earning only 18s. 6d. a week. In 1890 he was elected paid organizer for the Larkhall district and owing to his activity the Lanarkshire Miners' Union soon reached a membership of 30,000. He took a prominent part in the formation of the Scottish Coal Trade Conciliation Board and its satisfactory results were largely attributable to his efforts. His abilities as a leader caused him to rise steadily from the chairmanship of the Scottish Trade Union Congress to the first presidency of the parliamentary committee of the Scottish Trade Union Congress and in 1894 he became permanent president of the Scottish Miners' Federation. In 1912 he was elected to the presidency of the Miners' Federation of Great Britain and the building up of this body has been the great work of his life. Politically his success has not been so great as on the industrial field and although he stood as a candidate for Parliament seven times he was never elected. His greatest poll was 3,847 in a three-cornered fight at Mid-Lanark in 1910. In 1885 he was elected a member of the district school board for Larkhall, a position which he filled for 20 years. His work on the Coal Industry Commission from March till June 1910 brought him into greater prominence, but he became very ill in Nov. 1910. In March 1920, as his health was no better, he tendered his resignation from the presidency of the Miners' Federation, but the Federation refused to accept it and gave him leave of absence instead. In March 1921 ill-health compelled him to resign from the Federation and retire from public life.

SMITH, ALFRED EMANUEL (1873-), American politician, was born in New York City, Dec. 30 1873. The son of humble parents, his father being a truck driver, he was educated in the St. James parochial school and for several years was employed in the Fulton Fish Market. He was very popular with his associates and at the age of 29 was offered the Democratic nomination for the N.Y. State Assembly by the Tammany leader of the district in which he lived. He was elected for 1903 and by re-election served for 12 years. In 1911 he became Democratic leader in the Assembly and was appointed vice-chairman of the Factory Investigating Committee which made a searching inquiry into industrial conditions in the state, resulting in remedial legislation. In 1913 he was speaker of the Assembly. In 1915 he was chosen a delegate to the State Constitutional Convention, taking an active part in its proceedings. He opposed the constitution as finally revised, one reason being that it contained a provision designed to pre-

vent New York City from having a majority of legislators. He "stumped" the state against its adoption and it was overwhelmingly rejected. The same year he was elected sheriff of New York county, then a lucrative post because of the system of fees (later abolished), and in 1917 president of the Board of Aldermen of New York City. In 1918 he was elected governor of New York, defeating Charles S. Whitman. As a member of the Assembly he had been a strong supporter of woman suffrage, and in June 1919, as governor, called a special session which ratified the woman suffrage amendment to the Federal Constitution. In 1920 he was again the Democratic nominee for governor, but was beaten in the overwhelming Republican landslide of that year; he lost, however, by only 73,000 votes, whereas the Democratic candidate for president was at the same time defeated by a million votes in New York state—a remarkable testimony to his own personal popularity.

SMITH, ALFRED HOLLAND (1863-), American railway official, was born in Cleveland, O., April 26 1863. He began work on the New York Central railway system as a messenger boy in 1879. After serving as a foreman of construction and in various capacities in the engineering department, he was in 1890 appointed superintendent of the Kalamazoo division of the Lake Shore & Michigan Southern railway. He was successively division superintendent, assistant general superintendent and general superintendent of the Lake Shore road. In 1902 he became general superintendent of the New York Central railroad; in 1906 vice-president of the New York Central system; and in 1914 president. When the American railways were taken over by the U.S. Government Dec. 27 1917, he was appointed assistant director-general and it was he who worked out the form of central and regional administration under which the railways of the country were managed during the 26 months of Government operation. His aim, in which he succeeded, was to keep the management of the roads with their 2,000,000 employees, nearly all voters, in the hands of practical railway-men and, above all, out of politics. He divided the country into two regions and later into seven, each region being in charge of a railway officer of experience and reputation, he himself taking charge of the most important region, the Eastern. These regional directors had complete authority and only broad matters of policy and inter-regional questions were handled by the central (political) administration at Washington. In this way the railways were conducted throughout the war without great blunders or disorganization. On the completion of this important national service he was re-elected president of the New York Central Lines in June 1919. It was largely due to him that the New York Central Lines were greatly strengthened in operating efficiency and financial credit.

SMITH, FRANCIS HOPKINSON (1838-1915), American author, artist and engineer (see 25.260), died in New York City April 7 1915. His later writings included *Kennedy Square* (1911); *The Arm-Chair at the Inn* (1912); *Charcoals of New and Old New York* (1912); *In Thackeray's London* (1913) and *In Dickens' London* (1914).

SMITH, SIR GEORGE ADAM (1856-), British divine (see 25.261), was knighted in 1916, and from 1916 to 1917 was moderator of the general assembly of the United Free Church of Scotland. His later works include *The Early Poetry of Israel* (1912); *Atlas of the Historical Geography of the Holy Land* (with J. G. Bartholomew, 1914) and *Syria and the Holy Land* (1918).

SMITH, THEOBALD (1850-), American pathologist, was born at Albany, N.Y., July 31 1850. He was educated at Cornell (Ph.B. 1881) and at the Albany Medical College (M.D. 1883). In 1884 he was appointed director of the pathological laboratory of the Bureau of Animal Industry, in Washington, where for 11 years he investigated infectious animal diseases. At the same time he was professor of bacteriology at Columbian, later known as George Washington, University. From 1895 to 1915 he was director of the pathological laboratory of the Massachusetts State Board of Health, and after 1896 was professor of comparative pathology at Harvard. In 1915 he was appointed director of the department of animal pathology of the Rockefeller Institute for Medical Research, New York. He

made important contributions to the relation between human and bovine tuberculosis.

His numerous scientific papers include *Investigations into the Nature, Causation, and Prevention of Texas or Southern Cattle Fever* (1893); *Investigations Concerning Bovine Tuberculosis with Special Reference to Diagnosis and Prevention* (1894); *Investigations of Diseases of Domesticated Animals* (1897); *The Agglutinative Affinities of Related Bacteria Parasitic in Different Hosts* (1903) and *Certain Aspects of Natural and Acquired Resistance to Tuberculosis and Their Bearing on Preventive Measures* (1916).

SMITH COLLEGE (see 25.273).—Between 1910 and 1921 Smith College added to its equipment Burton Hall for biology, and the number of dwelling houses for students increased from 16 to 33. The library in 1920 contained 82,000 volumes and the Hillyer Art Gallery had increased its endowment to \$100,000 and added largely to its collections. The college abandoned the system of admission by certificate and all students enter by examination. In 1910-20 there were 181 teachers and 2,001 students, of whom 31 were graduate students, and the endowment was \$3,157,000, the total assets being over \$6,000,000. A campaign for increased endowment was carried on in 1920, with the result that, when the promises were realized, the assets of the college would be over \$9,000,000. The college publishes, besides its permanent bulletin, the *Smith College Studies* in history, modern languages and classics, and contributions of the department of biology. President Seelye was succeeded in 1910 by Marion LeRoy Burton (b. 1874), a graduate of Carleton College, Northfield, Minn., and Yale Divinity School, who resigned in 1917 and was succeeded by William Allan Neilson (b. 1869), a graduate of Edinburgh and Harvard Universities. In the World War the Smith College Relief Unit, the pioneer among American college women's units overseas, worked in 16 villages in the Somme, France, affiliated with the American Fund for French Wounded, and later with the Red Cross, from July 1917 until April 1920, with the exception of the period after the retreat of March 1918 until the following Jan., when the unit operated clubs and canteens and assisted in the hospitals at Beauvais and later behind the American front at Château-Thierry, at Nancy, and in the Argonne. A small group of the Relief Unit worked with the refugees at Orléans in the autumn of 1918. Three Smith Canteen Units were organized and operated under the Y.M.C.A. in France. Another small group worked as a Smith Unit with the Near East Relief in Armenia. (W. A. N.)

SMITH-DORRIEN, SIR HORACE LOCKWOOD (1858-), British general, was born May 26 1858. He joined the army in 1876, took part in the Zulu war and in the Egyptian campaign of 1882 and, attached to the Egyptian army, served at Suakin in 1884 and afterwards on the Nile in 1885-6, for which he was given the D.S.O. He took part in the Tirah campaign of 1897-8 and, showing conspicuous skill in handling troops, was rewarded with a brevet lieutenant-colonelcy. Immediately afterwards he was summoned to the Sudan to take part in the final advance to Khartum; for this he was promoted brevet colonel. He went out to the Cape in command of his regiment in 1899 and was shortly afterwards given a brigade and promoted major-general; he remained in the field in S. Africa, taking part in numerous operations, until the end of 1901, when he was appointed adjutant-general in India. From 1903 to 1907 he acted, first as a district, and afterwards as a divisional commander, being promoted lieutenant-general in 1906. He was then brought home to take up the command at Aldershot, an appointment which he filled with marked success until 1912, when he was transferred to the Southern Command; he was promoted general that year.

On the death of Gen. Grierson in Aug. 1914 while the Expeditionary Force was still assembling in France, Sir H. Smith-Dorrien (who had been given the G.C.B. in 1913) was appointed commander of the II. Army Corps. At Mons, and during the subsequent retreat, the brunt of the enemy's onsets fell upon his troops, and when hard pressed near Le Cateau he found himself obliged to halt and to give battle; by his resolute action he effectually checked pursuit, although his losses were somewhat heavy. He subsequently commanded his corps at the battle of the Marne,

on the Aisne, and during the severe fighting in Flanders in Oct. and Nov. On the splitting up of the Expeditionary Force into two armies he was appointed to the command of the II., receiving the G.C.M.G. for his services. This position he occupied until April 1915, when he returned to England and was placed in charge of one of the Home Defence armies. In the following Nov. he was chosen to take charge of the operations against German East Africa, but he fell ill on the voyage out, was unable to take up the command, and had to return home. He was appointed lieutenant of the Tower in 1917 and in 1918 became governor and commander-in-chief at Gibraltar.

SMOOT, REED (1862-), American politician, was born at Salt Lake City, Utah, Jan. 10 1862. He was educated in his native town and at the Brigham Young Academy, Provo, Utah. He amassed considerable wealth as a banker and woollen manufacturer. In 1895 he was appointed one of the presidency of the Utah Stake of the Church of Jesus Christ of Latter Day Saints (Mormon), and in 1900 was made an apostle. He was elected to the U.S. Senate from Utah in 1902 and re-elected in 1908, 1914, and 1920. In 1903 attempts were made to prevent his entering the Senate because of his connexion with the Mormon church, and on the charge that he personally favoured polygamy and even that he himself was a polygamist. He was allowed to take his seat; but the matter was placed in the hands of the Senate Committee on Privileges and Elections for further investigation. In June 1906 the Committee by a vote of 7 to 5 recommended that he be unseated; but as the personal charges against him had not been proved the Senate in Feb. 1907 by a vote of 42 to 23 refused to remove him. In 1910 he was chairman of the Republican Senatorial Campaign Committee. In 1921 he was a leading advocate of the adoption of a sales-tax, but failed to obtain its acceptance by the Senate, though the movement was widely favoured in business circles.

SMUTS, JAN CHRISTIAN (1870-), S. African statesman, of Dutch descent, was born at Cape Town in 1870, the son of J. A. Smuts, member of the Legislative Assembly for Malmesbury, Cape Colony. He was educated at the Victoria College, Stellenbosch, at the Cape University, and then went to Christ's College, Cambridge, where he took a "double first" in the Law Tripos in 1894. In 1895 he returned to Cape Town and practised as an advocate of the Supreme Court of the Cape till the end of 1896, when he went to Johannesburg to practise as an advocate there. The rapidity of his success is shown by his appointment as State Attorney to the Transvaal Republic in 1898. Thus before he was 30 his remarkable ability was acknowledged and, though he was opposed to the policy of President Kruger, his hand is to be recognized in the State documents of the Transvaal during the critical period which ended in the sending of the ultimatum to Great Britain and the outbreak of the S. African War of 1899-1902. During that war Smuts served throughout with Boer forces, rising during its latter period to the rank of general, and to the authority among his own people of one who had shown the possession of gifts as a leader in the field as brilliant as those which he was known to possess in the realm of the law. Thus when the negotiations for peace began Smuts stood out as one of the recognized Boer leaders.

With Gen. Botha, he threw his influence during the negotiations into the scale for peace, and when, in 1907, responsible government was granted to the Transvaal, Smuts became the right-hand of Gen. Botha, the first Prime Minister of the Transvaal, in the Ministry which he then formed. As colonial secretary the bulk of the administrative work of the new Ministry fell to him, and his success as an administrator was then proved beyond subsequent doubt. He brought to his task an intellect of the first calibre—keen, quick, penetrating. His industry was untiring. Already a man of the world, he commanded the admiring devotion of his subordinates. These gifts would have secured for Smuts a position of great influence in any Ministry. They were no more than one of Smuts' many claims to such a position in the Botha Cabinet. He showed at once that he had high parliamentary ability. His rapid brain made him a master in debate. The complexities of legislation had no diffi-

culties for him. His mind had a natural bent towards compromise on unimportant points, and he showed again and again an almost uncanny gift for producing at a moment's notice the form of words that would give body to such compromises. His loyalty to, and affection for, Gen. Botha strengthened an influence thus already very strong, and when in 1900 the S. African National Convention met to draft an instrument for the union of the four S. African colonies, Smuts went to it as a delegate from the Transvaal with a reputation for ability and capacity second to that of no other delegate. High as it was, this reputation was enhanced by his work at the Convention. He had gathered round him a staff of experts, had thought out a scheme of union, had worked out its details, was prepared to put this framework before the first meeting. Such foresight had its reward, the more because it was buttressed during the debates of the Convention by the same readiness in debate, the same clear recognition of essentials, the same natural disposition towards compromise on details, and the same quickness in producing verbal formulæ, as Smuts had already shown in the Transvaal Parliament.

When union was accomplished Smuts became for S. Africa what he had been for the Transvaal—the right-hand of Gen. Botha, the first Prime Minister of the Union. His success, both administrative and parliamentary, in the Transvaal was repeated as a minister of the Union. As Minister of the Interior, of Mines, and of Defence, he bore the lion's share of the early administrative work of the Union. His Defence Act, passed in 1912, was a model of organization, and the speech in which he moved its second reading in the Union House of Assembly established his reputation throughout S. Africa.

Thus on the outbreak of the World War in 1914, when Gen. Botha declared for the most loyal support of the British Government, the bulk of the burden of organizing the military forces of the Union fell upon Smuts. It was sustained with complete success. The expedition against German S.W. Africa, and the crushing of the rebellion in the Union in 1914, both bore testimony to his capacity as an organizer of victory. He took command of the Union columns invading German S.W. Africa from the S. and carried through that part of the campaign with great boldness of strategy and complete success. Then Botha and Smuts turned to other fields of war. Expeditionary forces were organized against German E. Africa and to take part with the Allies in the fighting on the western front in Europe. In Feb. 1916 Smuts was appointed by the British Government commander-in-chief of the Imperial forces operating in German E. Africa. He had been offered the appointment in Nov. 1915, but had then declined. When he took command, the operations against German E. Africa had reached a state of stalemate. He conducted his campaign with great vigour, exacting from his troops heavy sacrifices of long marching in that trying climate, and before the end of 1916 he had reduced the German forces to the position of fugitive bands. Then another duty called him away from E. Africa. At the end of 1916 Mr. Lloyd George became Prime Minister of Great Britain and at once summoned the Imperial War Cabinet. General Smuts went to it as the representative of S. Africa. So useful did he prove himself to be in that position that he became the only permanent Dominion member of the Imperial War Cabinet. With Botha he represented S. Africa at the Peace Conference in Paris, and returned to S. Africa after peace was signed, only to lose Botha almost immediately and to find himself, by the sudden death of his leader and close friend, Prime Minister of the Union in Sept. 1919.

The political position in S. Africa was menacing. The Nationalist agitation, led by Gen. Hertzog, had grown among the Dutch-speaking people during the war. Resentment at being involved in the quarrels of Europe had fed it. The old passion of the Dutch of S. Africa for peaceful isolation had revived in full strength. Smuts speedily made up his mind that the sense of the country must be tested by a general election. It took place in the spring of 1920 and left Smuts and his party without the semblance of a clear majority in Parliament. Smuts

held office by the grace of the Unionists. He had no doubt as to the needs of his position. S. Africa required an established Government; it must be formed by combination between his followers and one of the other parties. His natural impulse was for reconciliation with the Nationalists, and he sought reconciliation with them, but on one clear condition. They must repudiate their Republican aims; and S. Africa must remain willingly a state of the British group of nations. This condition the Nationalists refused. Then Smuts turned to the Unionists, who throughout the war had supported the Botha Ministry as the one safeguard of membership for the S. African state of the British Commonwealth of Nations. With ready self-sacrifice the Unionists accepted his invitation. The two parties were joined into one, the Unionists becoming members of the S. African party, which had been Botha's party and was now led by Smuts. The general election of March 1921 followed, and gave the new party a decisive victory at the polls and a clear and substantial majority in the Parliament of the Union. (B. K. L.)

SMYTH, ETHEL (1858—), English musical composer, was born in London on April 23 1858, the daughter of Gen. J. H. Smyth. She began her musical studies at Leipzig in 1877, becoming a pupil of Heinrich von Herzogenberg, then conductor of the Bach Verein, whose wife was an intimate friend of Johannes Brahms. She was thus thrown from the first into a highly intellectual musical society. Her earliest works, principally chamber music, were performed at Leipzig; her first orchestral works being produced by (Sir) August Manns at the Crystal Palace concerts and the symphony concerts started in 1886 by (Sir) George Henschel. She also produced a Mass, performed in 1893 at the Albert Hall. Subsequently she turned her attention to opera, her first work in this direction being *Fantasio*, based upon a book by De Musset (produced at Weimar 1898 and revived at Karlsruhe 1901). This was followed by *Der Wald*, produced at Dresden in 1901 and at Covent Garden, London, in 1902, and New York 1903; and *The Wreckers*, produced under the title "Strandrecht" at Leipzig and Prague in 1906, at His Majesty's theatre, London, in 1909, and at Covent Garden in 1910. Her opera, *The Boatswain's Mate*, written for a German theatre, but, owing to the war, not produced there, was produced in London in 1915, and was revived in 1918 and met with considerable success. She also published in 1907 a series of songs with instrumental accompaniment, and in 1913 four orchestral songs. Miss Smyth, who received the degree of Mus. Doc. from Durham University in 1910, became known as a leading militant suffragette, and, besides other music written for the cause, produced *The March of the Women* (1911). In 1910 she published two volumes of brightly written autobiography and reminiscences under the title *Impressions that Remained*, and in 1921 another book, *Streaks of Life*. On Jan. 1 1922 she was created D.B.E.

SMYTH, HERBERT WEIR (1857—), American classical scholar, was born at Wilmington, Del., Aug. 8 1857. He was educated at Swarthmore (A.B. 1876), Harvard (A.B. 1878), Leipzig, and Göttingen (Ph.D. 1884). During 1883-5 he was instructor in Greek and Sanskrit at Williams College, and then for two years was reader in Greek at Johns Hopkins. From 1887 to 1901 he was professor of Greek at Bryn Mawr. In the latter year he was called to Harvard as professor of Greek and in 1902 was appointed Eliot professor of Greek literature, succeeding William Watson Goodwin. During 1899-1900 he was professor of the Greek language and literature at the American Classical School at Athens. From 1889 to 1904 he was secretary of the American Philological Association and editor of its *Transactions* and in 1904 was elected president. He became a fellow of the American Academy of Arts and Sciences, a member of the American Philosophical Society and vice-president of the Egypt Exploration Society.

His works include *The Sacred Literature of the Jains* (1894, a translation); *The Ionic Dialect* (1894); *Greek Melic Poets* (1900); *Greek Grammar for Schools and Colleges* (1915); *Greek Grammar for Colleges* (1920). He was also author of *The Greek Language in its Relation to the Psychology of the Ancient Greeks* (read before the Con-

gress of Arts and Sciences at the St. Louis Exposition in 1904); "Aspects of Greek Conservatism" (in *Harvard Studies in Classical Philology*, 1906); "Greek Conceptions of Immortality from Homer to Plato" (in *Harvard Essays on Classical Subjects*, 1912) and various contributions to philological journals. He was editor of the *Greek Series for Colleges and Schools* (20 vols.).

SNOWDEN, PHILLIP (1864–), British Labour politician, was born at Cowling, Yorks, July 18 1864. He was educated partly privately and partly at a board school, and in 1886 entered the Civil Service. In 1893 he retired, and devoted himself to journalism and lecturing, becoming well known for his ardent advocacy of extreme socialistic views. He unsuccessfully contested Blackburn in 1900 and Wakefield in 1902, and in 1903 he became chairman of the Independent Labour party. He held this position until 1906, and in that year was returned as Socialist member for Blackburn. He sat on various royal commissions, including those on the Civil Service and Venereal Diseases, and from 1917 to 1919 was again chairman of the Independent Labour party. Mr. Snowden made himself extremely unpopular during the World War owing to his pacifist opinions, and was one of the Socialist members of Parliament who lost their seats at the general election of 1918. He had married in 1905 Miss Ethel Annikin, who became well known as a speaker and writer on social subjects. In 1920 she went to Russia as a member of one of the various Labour delegations invited to inspect Soviet conditions of government. She published on her return an account of her experiences, under the title of *Through Bolshevik Russia* (1920).

SOCIALISM (see 25.301*).—Socialism is at once a theory, or rather a whole body of theories, and a movement, or rather a number of movements more or less closely connected. The name has been used during the past century to describe many different social theories, in all of which a common character has been perceived. In recent times it has come to be used less with reference to any definite theory than for the purpose of describing the movements in various countries which have adopted the name or have declared their adhesion to Socialism. It is thus possible, in setting out to give a summary account of Socialism, to describe it either by its connotation, that is to say, in terms of the ideas for which it stands, or by its denotation, that is, in terms of the groups and parties which profess allegiance to it. But neither of these methods of description is by itself satisfactory, nor is it possible by either, or even by a combination of both, to arrive at a satisfactory or adequate definition of Socialism. The word is used, and has been used increasingly in recent years, in a number of different and frequently overlapping senses. It has changed its meaning with time: but the changes have not served to clarify it, but rather to increase the number of different senses in which the term is used.

It would be well to begin by ruling altogether out from the scope of this article certain popular uses of the term which have been current especially during the past generation. The well-known phrase, "We are all Socialists now," and the constant references to "socialistic legislation," only serve to obscure the real meanings which attach to the word. When it is said that, "We are all Socialists now," all that is meant is that everybody nowadays is prepared to agree that a greater measure of governmental intervention both in industry and in the affairs of society generally is necessary than was currently regarded as necessary or even possible 100 years ago.

The phrase "socialistic legislation" again is frequently used to cover almost any extension of governmental activity in the sphere either of industry or of provision under the State or under local government auspices for the needs of the people. The phrase "socialistic taxation" is used, with a greater approximation to accuracy, in reference to those forms of taxation which aim not merely at producing revenue for the public authorities, but at bringing about an actual readjustment in the distribution of income in the community, arrived at by the unregulated operation of capitalist economic forces. Again, almost any extension in the sphere of local government action, such as the taking over of a tramway system or the establishment of banking or insurance facilities by a local authority, is frequently referred to as

"municipal socialism," even if the public body which inaugurates this policy does not consist of members who profess any allegiance to, or have any sympathy with, the doctrines of any Socialist party or group. All these and similar uses of the word "Socialism" are here ruled out of consideration.

The word "Socialism" first came into use in the third or fourth decade of the 19th century in England and France. The first-known literary reference to it occurs in the "Poor Man's Guardian" in 1833; but it is believed that the word was occasionally used at an earlier date in both France and England. In Great Britain it was most frequently used during the first half of the 19th century in reference to the doctrines associated with the name of Robert Owen and his disciples, and to the theories of the anti-capitalist economists, such as W. Thompson, who were largely affected by Owenite teaching. In France the name similarly attached itself to the doctrines of thinkers of whom the most important were followers of St. Simon and Fourier. Its use then spread much more rapidly on the continent of Europe than in Great Britain, and it was mainly in connexion with the growth of continental Socialist movements (Louis Blanc in 1848; the First International Working Men's Association in the 'sixties and the Paris Commune of 1871) that it was used by English writers, until it was reimported into Great Britain as the name applied to a constructive body of doctrines in the early 'eighties, especially under the auspices of H. M. Hyndman and the Democratic Federation (subsequently the Social Democrat Federation).

It is important to realize that in all its modern meanings the word "Socialism" refers definitely to doctrines and movements which owe their rise to the growth of large-scale production and the capitalist system in industry. It is, indeed, sometimes applied to theories and Utopian speculations, such as those of Sir Thomas More, which have no direct reference to any particular stage of social evolution and are merely attempts to outline the structure of an ideal commonwealth. But, although such Utopias as those of Plato and More may present features of resemblance to the doctrines of modern Socialism, there is no real connexion between these and the theories or attitudes towards property which are sometimes comprehended under the terms "mediaeval Socialism" and "mediaeval Communism." Socialism, as a body of doctrine and as a movement applicable to modern conditions—and these are the senses of the term which matter to the student—made its appearance when the changes in methods of production and transport, which are usually described as the "Industrial Revolution," had created the modern working class or "proletariat," and had caused this class to make the attempt to organize for common protection against the evil effects of new industrial conditions.

Modern Socialism, although it has claimed many adherents belonging to other classes, is thus essentially a working-class or "proletarian" movement, in that it is based upon and directly due to the rise of the "proletariat" as a distinct social class capable of independent class organization and suffering under a sense of injustice and inhibition. The Socialism of the Owenite period serves in certain respects very clearly to reveal this essential character of the movement. Owen himself has indeed been described by subsequent social thinkers—by Marx, for example—as a "Utopian" Socialist; but the rise of the Owenite movement is very clearly and directly traceable to the actual economic conditions of the early 19th century. It was out of his experience as a factory manager and owner at New Lanark and elsewhere that Owen developed his Socialist doctrines; and, in the minds of most of his followers even more than Owen himself, these doctrines possessed always a close and definite relation to the rise of the working class to social consciousness and to the possibility of social power. Thus, while Owen was expounding his doctrine of ideal Coöperative or Socialist communities, and endeavouring to demonstrate by practical experiment possibilities of achieving Socialism by the foundation of such communities in the midst of a rapidly developing capitalist environment, many of those who were most affected by his doctrines were engaged either, as economists, in developing their critique of the current economic theories based on capitalism, or,

* These figures indicate the volume and page number of the previous article.

as leaders in the new-born working-class movement, in endeavouring to organize the "proletariat" for the winning of control over industry and over the machinery of Society. The Grand National Consolidated Trades Union, in which Owenite ideas played so large a part, was organized by men who were aiming not merely at the protection of the working class in face of the adverse conditions created by the new factory system, but at a definite transformation of the industrial order and the winning of control over industry for the "productive classes." This aim was even more clearly defined in the other great "Owenite" union of the period, the Builder's Union, and its abortive plan of 1833 for the formation of a Grand National Guild of Builders. The Chartist movement, which was largely influenced by Owenite and Socialist ideas, was definitely aiming at the conquest of political power by the organized working class with a view to social transformation.

Socialism in Great Britain thus came into existence as: (1) a challenge to the orthodox economic theories of Ricardo and other writers; and (2) an attempt to win power in Society for the organized working class. It was, however, left for later thinkers, and above all for Karl Marx (1818-83), to take up where they had been dropped by the original English pioneers both the anti-capitalist economic teachings and the endeavour to build up the working-class movement into a constructive force aiming at the transformation of the social order. The Socialism of Karl Marx is frequently contrasted with the Socialism of previous thinkers as being "scientific," whereas their Socialism was "Utopian." But, in fact, Marx's Socialism was very largely based upon that of the earlier thinkers and working-class leaders, although he for the first time formulated into a definite system the views and the policy which they had only suggested and sought after.

All modern Socialism, even that of the schools which repudiate or at least profess no allegiance to Marx, has been profoundly influenced by him. This applies even to those schools of Anarchist Communists and French and Italian Syndicalists who seem to have least in common with Marxian teaching; for, even in their case, many Marxian ideas have blended with the ideas which they have derived from other Socialist and quasi-Socialist thinkers, such as P. J. Proudhon; and, although they have interpreted the Marxian teaching differently, a great deal of it has found its way into their systems and policies.

Marx's first important contribution to Socialist thinking, *The Communist Manifesto* (1847), which was drafted jointly by him and Friedrich Engels, is generally recognized as the starting point of the modern Socialist movement. His *Das Kapital*, of which the first volume was published in 1867, is the working-out into a system of the most vital ideas originally presented in *The Communist Manifesto*. These works have, of course, been translated into practically all European languages, and their ideas have generally passed into the common stock of European Socialist thought. This has hitherto been true of Great Britain in a less degree than of any other important industrial country; but even English Socialism began in the 'eighties on an essentially Marxian foundation, and, although Marx fell into disfavour with British Socialists in the 'nineties and in the earlier years of the present century, there has recently been an important revival of the study of his works among the more radical section of the British working-class movement. In other countries the organized Socialist movement is in practically all cases definitely Marxian, and bases its thinking and its propaganda throughout on Marxian terminology and Marxian ideas. Thus we find that, as divergent currents have again and again appeared in European Socialism, the name of Marx and his fundamental conceptions have been invoked, for the purpose of justifying widely divergent policies and conceptions. During the past few years, for example, a great pamphleteering controversy has been proceeding between Nikolai Lenin on the one side and Karl Kautsky on the other, representing two very different tendencies in European Socialism. Each of these writers bases his contentions on an almost theological reverence for the words of Marx, and seeks to justify his position by copious quotations from Marx's books and manifestos.

In the criticism which has been directed against Marx by orthodox economists in many countries, attention has been paid mainly to his theory of value, and only in a considerably less degree to his theory of history. This is unfortunate; for there is no doubt that the theory of value has played a quite secondary part to the so-called "materialist conception of history" in the influence which Marx's teaching has exercised on the modern working-class movement. The theory of value, as it was presented by Marx, and his attempt to build a theoretical economic system on the idea of labour as the source of value and exploitation as consisting in the appropriation by a privileged class, the owners of the means of production, of the surplus value created by labour, was mainly a criticism and inversion, to suit Socialist ends, of the current economics of Marx's own day. Like Thompson and the earlier English economists to whom he owed so much, Marx took the Ricardian theory of value and drew from it conclusions by no means acceptable to orthodox economic theorists. Undoubtedly his ideas of "surplus value," and exploitation resulting from the individual appropriation of "surplus value," played an important part in creating the sense of injustice and oppression among the workers; but by themselves they would never have sufficed to give Marx his dominant position as the theorist of modern Socialism.

This position depends far more on his theory of history, the effect of which was to give to those members of the working class who encountered his teaching the sense of possessing a mission and of having on their side the great world forces of social transformation. Interpreting historical changes as the result of the operation of economic forces, Marx insisted that to each stage in the evolution of the means of production there corresponds an evolution in the forms of political society and in the class structure of society. The industrial system of the 19th century, he claimed, had called into existence a new social class, the property-less, wage-earning "proletariat"; for, although there had been capitalists and wage-earners in earlier stages of social evolution, the economic structure of Society had not before been based upon the dominance of the capitalists as a class. Nor had the "proletariat" been called into existence as a class, confronting the possessing capitalists throughout the industrial system in all the countries of the world which had reached the capitalist phase. The next stage in social evolution, according to Marx, would be the rise to power of the "proletariat," and, just as the capitalists had risen to power and displaced or absorbed the privileged classes with which social authority had previously rested, so the "proletariat" under the system of large-scale industry would improve its organization and increase its strength until it was able to do battle with, and to overthrow, the capitalist class. In expounding this theory of "economic determinism" or the "materialist conception of history," Marx made a number of prophecies concerning the actual future of capitalist industrialism which have not thus far been at all completely verified. The progressive elimination of the small capitalist, the aggregation of the control of capital into fewer and fewer hands, the progressive "misery" of the "proletariat," which Marx prophesied, are forecasts in which truth and falsehood are intertwined. But these prophecies concerning the actual course of events are in no sense vital to his central idea, which is that of the gradual rise to power of the "proletariat" or working class, and the conquest by it of economic authority, resulting necessarily in the transformation of the political structure of Society and in the abolition of social classes.

It is easy to see that this doctrine was bound to exercise a strong fascination over the minds of those men and women of the working classes who were brought into contact with it. Whereas, without some such theory they were conscious only of the enormous strength of the forces to which they were subject, and of their manifest weakness as almost property-less wage-earners, living in constant insecurity, at the mercy of trade fluctuations which resulted periodically in widespread unemployment, Marx gave them the sense of fulfilling an historic mission, and of having on their side a world-force far more powerful than the huge economic and political strength which seemed to be in

the possession of the ruling classes of the day. It is this one thing, and one thing only, that explains the veneration in which Marx is held throughout practically the whole Socialist movement. It was he, who, more than anyone else, gave the working class a sense of power, and imported into their efforts towards organization and concerted resistance to the evils to which they found themselves subject a conscious purpose not merely of combating capitalism, but also of replacing it.

In the earlier article some account was given of the rise of Socialist parties in various European countries. This rise continued at an increasing pace in later years, a great impetus having been given to the Socialist forces in almost all parts of Europe by the circumstances of the World War.

There was in 1921 in every industrialized country at least one Socialist party, possessing in the majority of cases a considerable representation in its national Parliament. Indeed, in many countries there had come into being more than one Socialist party; for the process of unification of Socialist political forces which had been proceeding steadily up to the outbreak of the war gave place to a separatist tendency, which resulted in a regrouping of forces in most of the countries in which the movement was strong. The first cause of these divisions was the attitude of Socialists towards the outbreak of the World War. In almost all belligerent countries the Socialist parties became divided over the issues of the war. In some cases these divisions of opinion resulted in actual cleavages within the various parties; in others the parties held together, but acute divisions of opinion continued inside them. These differences were greatly accentuated by the Russian revolutions of 1917, which inevitably exercised a very powerful influence on Socialist opinion throughout the world. Just as, in its earlier days as an organized political movement, Socialism always tended to look back to the Paris Commune of 1871, it now even more definitely looks back to the Russian revolutions of 1917, upon which the most acute divisions of opinion in the world of Socialism to-day are based. Any attempt, therefore, to analyze the forces at work in the Socialist movement of the various countries in 1921 must begin by taking into account the new alignment of opinion caused by the Russian revolutions.

The first Russian revolution of 1917 was universally acclaimed by Socialists throughout the world. It meant for them the overthrow of Tsardom and the destruction of the most powerful and complete absolutist monarchy left in the world. Moreover, refugees from Russia had played an important part in the Socialist movement in almost all countries in which it had become organized. It was not the first of the Russian revolutions but the *coup* of Nov. 1917 that divided acutely the Socialists of the various countries. Everywhere the left wing of the Socialists acclaimed the Bolshevik Revolution, while the right wing was hostile to what it regarded as the overthrow of the "democratic" institutions which had been introduced under the Kerensky regime.

During the following years, from 1918-21, the differences within the Socialist ranks resulting from the Bolshevik Revolution were steadily accentuated. Under the auspices of the Russian Bolsheviks, or Communists as they now call themselves, with a definite reference back to *The Communist Manifesto* of 1847, a new international organization of Socialism, the Third or Moscow International, was inaugurated, and an appeal was made to the "proletariat" in all countries to rally to this new body, of which the fundamental ideas were the overthrow of the capitalist regime by the intensive prosecution of the class war, involving the use of force, and the assumption by the "proletariat" of dictatorship over Society during the "transitional period," which would be necessary both for the combating of the attempts of the "counter-revolution" to regain power, and for the laying of the foundations of a Socialist or Communist society free from class distinctions. During the years after the Bolshevik Revolution these Communist doctrines gradually spread over Europe, and resulted in the formation in most countries of Communist groups and parties of varying degrees of importance. Sometimes these began by working as groups within the existing Socialist parties, and sometimes they succeeded in winning over to their side a majority of the older Socialist parties, which thus

became Communist. In other cases, however, the Communists, unable to command a majority in the Socialist parties in other countries, founded new and rival parties of their own.

Thus in 1921 the position of European Socialism was extraordinarily complicated, as a reference to the state of affairs in a few of the principal countries will readily indicate. In France the Communists had succeeded in securing a majority in the ranks of the French Socialist party, and it had thereupon changed its name to the French Communist party. The minority, which refused to accept the change in name and policy, thereupon reformed the Socialist party as a coalition of right wing and central elements. In Italy the Socialist party, which was throughout opposed to Italian participation in the war, at first affiliated to the Moscow International; but subsequently differences arose as to the strategy to be adopted, and these led to a split in the ranks of the party, the extreme Communists, who were in a minority, seceding and forming a Communist party of their own, while the right and centre, including many Communists, held together as the Italian Socialist party. In Germany the Social Democratic party split during the war. A majority section of the party supported the German Government in the prosecution of the war and voted war credits. Gradually a minority party formed, and finally the anti-war elements left the Social Democratic party and formed the Independent Socialist party. After the Bolshevik Revolution in Russia two small Communist parties were also formed in Germany. In 1920 the majority of the Independent Socialist party resolved upon adhesion to the Moscow International and united with the Communist factions to form the German Communist party. The right wing of the Independent Socialist party continued in existence under the old name; and there were thus in Germany, in 1921, three distinct parties, Social Democrats or Majority Socialists, Independent Socialists, and Communists. In Great Britain the position was somewhat different; for political action was taken through the Labour party, a federation of trade unions, Socialist societies and kindred bodies. Of the Socialist societies, the British Socialist party, the direct descendant of the Social Democratic Federation, the earliest Socialist body in Great Britain, affiliated to the Moscow International and became the nucleus of a Communist party which applied for affiliation to the Labour party, but was refused. The Independent Labour party, which, unlike the Labour party as a whole, was hostile to participation in the war, nevertheless remained affiliated to the Labour party. There were thus only two groups undertaking political action in Great Britain—the Labour party, including the Independent Labour party, on the one hand, and the small, but militant, Communist party on the other.

These instances, drawn from a very much larger number, serve to illustrate the general character of the divisions which had arisen in the world Socialist movement since the Russian Revolutions of 1917. As the movement has been divided nationally, so a division has taken place in the international organization of Socialism. Before the war most of the Socialist parties of the world were loosely held together by the Congresses of the "Second International," of which the first was held in 1889. Out of the Congresses developed the International Socialist Bureau, which was formed in 1900. The Bureau was unable to function effectively during the war, both because communications were to a large extent interrupted, and because of the differences of opinion between and among the various national sections. Various attempts were made to secure united action by all the national Socialist parties; but, in face of the opposition of the Governments and of internal differences, these produced little result, the attempt to call an International Socialist conference at Stockholm in 1918 breaking down. The Socialist parties of the Allied countries, however, held a number of conferences, and drew up a declaration of war aims, which exercised a certain influence. Immediately on the conclusion of hostilities steps were taken to convene a full International Socialist conference, and an attempt was made to reform the pre-war Socialist International. The reformed body, however, known as the "Second International," never became, in face of acute differences

of opinion, at all fully representative, and during 1910 and 1920 there were numerous secessions from it, until it came to consist principally of the British Labour party, the German Social Democratic party (Majority Socialists), and the Socialist parties of a number of small countries such as Sweden, Poland, Belgium and Holland. A number of Socialist parties held aloof both from the Second and from the Third International, and these bodies in 1920 formed a provisional International "Working Union," of which the aim was the reconstitution at a later stage of a fully representative and inclusive Socialist International. This provisional body, sometimes known as the "Vienna International," includes the British Independent Labour party, the German Independent Socialist party, the French and Swiss Socialist parties, and a number of others. The Italian Socialists were in 1921 unconnected with any of the three Internationals.

There can be no doubt that the division of opinion in the Socialist ranks which is reflected in these divisions in national and international organization is very profound. With the growth of parliamentary representation, the political Socialist parties of the various countries have been becoming steadily more moderate and constitutional in their outlook. But the Moscow revolution, accomplished by insurrectionary methods and by "proletarian" direct action, represented a challenge to the constitutional political attitude of the more orthodox Socialist parties. Those which have rallied to the call of Moscow profess to be the only true inheritors of the Marxian tradition and the legitimate successors of the International Working Men's Association, or "First International," of 1864. It is still impossible in 1921 to forecast the result of the conflicts between this section and the older Socialist parties; but it seems likely that the divisions which have come into existence will be to a considerable extent permanent, even if the ultimate point of cleavage has not yet been discovered.

James Bonar on p. 301 of vol. 25 defines Socialism as "that policy or theory which aims at securing by the action of the central democratic authority a better distribution and, in due subordination thereunto, a better production of wealth than now prevails." It will be clear from what has been said above that this definition is certainly no longer adequate or correct in 1921, even if it could be regarded as adequate at the time at which it was made. It is as true now as then that all schools of Socialism are united in seeking a better distribution and also a better production of wealth; but it cannot be assumed that this is sought solely or even mainly "through the action of the central democratic authority," or that many Socialists would agree that any such body as a "central democratic body" exists in the community as it is organized to-day. Any present-day definition of Socialism would certainly have to emphasize the fact that it seeks not merely a better distribution and production of wealth, but a fundamental reorganization in the whole system of organized Society, political as well as economic. At the time when Bonar wrote, Socialists, especially in Great Britain, were largely engaged in combating the still prevalent doctrines of *laissez-faire* politicians and economists, and in seeking to emphasize the necessity for a greater measure of collective regulation of the social and economic life of the community. In Great Britain, more than elsewhere, many Socialists came to regard the political State, or machinery of government, as the principal instrument of this regulation, and to look forward to the transition to Socialism mainly through the nationalization, or transference to State ownership, of all vital industries and services, together with an extension of municipal ownership in the sphere of local public-utility services. This idea of the form of the transition to Socialism fitted in well with the stress which was laid, during the 'nineties and the earlier years of the 20th century, upon political action. This period witnessed the formation, first of the Independent Labour party, and then in 1900 of the Labour Representation Committee, which subsequently became the Labour party. It was also the period during which the Fabian Society, with its propaganda of political permeation, largely influenced British Socialism, and diverted it from the Marxism of its earlier development in the 'eighties.

But from 1910 onwards new currents of opinion were increasingly affecting these accepted dogmas of Socialism, both in Great Britain and elsewhere. Important, in this connexion, is the rise of the Syndicalist movement in France, which was at its zenith in the earlier years of the 20th century, and of the Socialist Labour party and the Industrial Workers of the World in the United States of America. There were important differences between the standpoints of French Syndicalism, which was derived largely from the semi-Anarchist doctrines of Proudhon and his school, and American Industrial Unionism, based by Daniel De Leon and his followers upon the large-scale and "trustified" American capitalist system. But they were alike in stressing rather the economic than the political character of the transition to a Socialist system, and in demanding more aggressive action by the workers in the industrial field. In Great Britain and in other European countries these doctrines, although they were not accepted in their completeness, exercised a powerful influence, seen especially in Great Britain in the rise of the Guild Socialist movement after 1912 (see GUILD SOCIALISM).

Whereas Syndicalism and, in some of its forms, Industrial Unionism directly challenged the utility of Socialist political action and demanded an exclusive concentration upon the industrial field, the Guild Socialists never took up this attitude, but sought, without disparaging political action, to secure an intensification of industrial activity, and in particular a change in the attitude of Socialists towards the problem of industrial control. Their influence in this direction has extended far beyond their own ranks, and it is not too much to say that the effect of the various movements possessing largely an industrial character—Syndicalism, Industrial Unionism, Guild Socialism, etc.—has been to bring about a revolution in Socialist thinking on this question. It is no longer assumed by Socialists that nationalization is necessarily desirable, or that the transference of industry to the State, even if it be accomplished by a political victory of Socialists, furnishes an adequate solution of the industrial problem. Most Socialists are agreed in desiring, in a greater or less degree, as an integral part of any Socialist system, the control of the administration of industry by the organized workers by hand and brain who are engaged in it.

Nor has this change in the attitude of Socialists towards the problem of industry been without its effect in other spheres of policy. As Socialism passed from its earlier revolutionary into its middle purely constitutional and political phase, it came gradually to be assumed that the realization of Socialism would involve only the capture of political power by the Socialist parties and the use of the existing machinery of Society—modified perhaps in certain particulars, but remaining essentially the same—for socialist instead of for individualist ends. There is now acute division of opinion on this question; but most Socialists are far more ready than in 1910 to agree that the realization of Socialism would involve not a mere conquest of political power and the assumption of control over the machinery of government by the workers, but also a profound transformation in the machinery of government itself. By Lenin and the Communists (see Lenin's *The State and Revolution* for the best statement of this point of view) the State is regarded as purely a "capitalist organ," the tool of a dominant class in Society. In the words of *The Communist Manifesto*, they regard the State as "an Executive Committee for administering the affairs of the whole governing class." Such an instrument, essentially coercive in its character, will in their view become unnecessary with the realization of Socialism. During the transitional period of "dictatorship" the "proletariat" will indeed require an instrument fully as coercive as the capitalist State. But the Communist view of the existing machinery of the State cannot be adapted for this purpose, but must be destroyed and replaced by a "quasi-State" based definitely and exclusively upon the power of the workers themselves. Gradually, as the realization of Socialism comes nearer, they hold that this "quasi-State" will "wither away" and give place to a free organization of Society in which "government," which they understand to imply a system based on coercion, will be replaced by "administration." Even among those Socialists

who do not accept this Communist view, keen criticism has been directed in recent times upon the structure of the present-day State and upon the conception of political democracy which was almost universally accepted in the 19th century. Universal political suffrage is no longer held to furnish any adequate basis, or even necessarily any basis at all, for truly democratic institutions; for it is pointed out that, as long as great inequalities of wealth and power exist in the community, and as long as the industrial system is based on an acute division of classes, this "political democracy" is in fact inoperative, since the power and wealth of the few can be used in order to prevent the will of the people from finding expression, and, indeed, to prevent the people from developing any conscious or clearly formulated will of its own. By the Guild Socialists and by many others of the newer schools of Socialist thought, stress is laid upon the importance of securing a system of democratic self-government in the industrial sphere as the necessary condition of democracy in politics or in Society as a whole.

These changes in the conception of Socialist aim and method have resulted in a much closer relationship between Socialist ideas and the definitely economic forms of working-class organization, such as Trade Unionism and Coöperation. No longer basing their hopes of Socialism entirely upon action in the political sphere, Socialists are driven more and more to rely on the development of the organizations created by the working classes themselves for the protection of their interests and standard of life under capitalism. Whereas the earlier Socialists appealed to Trade Unionists and Coöperators to realize the necessity for Socialism and to embark upon political action, the newer schools of Socialism are endeavouring also to influence the policy of the Trade Unions and of the Coöperative movement in the direction of Socialism applied to industry—that is, of the development and expansion of working-class industrial control (*see* TRADE UNIONISM and GUILD SOCIALISM).

The organization of the Socialist movement in Great Britain is often exceedingly bewildering to those who approach it for the first time. There are a large number of bodies of varying degrees of importance, and often with names which bear a close resemblance one to another. The Labour party, which is by far the largest political body, may be regarded as definitely Socialist in the sense in which the majority of continental European Socialist parties are Socialist. Its annual conference has repeatedly pronounced, in general terms, in favour of Socialism, and its policy on the whole coincides with that of the "right wing" Socialist parties of Europe. At the same time, its main strength is drawn from the trade unions. In 1920 it consisted of 126 affiliated trade unions with a total affiliated membership of 3,511,000. In addition it included the Independent Labour party and the Fabian Society and one or two smaller Socialist bodies. Locally it was organized in several hundred Local Labour parties, which in their turn consisted mainly of affiliated branches of trade unions, Socialist societies and kindred bodies. These Local Labour parties, under the new constitution of 1918, also admit individual members who accept the aims of the party. There is a very considerable individual membership enrolled in this way; but no figures are available. In 1920 the Labour party had 66 members in the House of Commons.

Apart from the Labour party, although in some cases affiliated to it, are the various Socialist societies, of which the largest is still the Independent Labour party, which has been mentioned above. This party had in 1920 35,000 members organized in local branches throughout the country. It had returned five members as Independent Labour party members to the House of Commons; and these sat as members of the Labour party. In addition a considerable number of members who were returned under the auspices of the trade unions, affiliated to the Labour party, belonged to the Independent Labour party.

Next in point of size stands the Communist party of Great Britain, formed in 1920 by a fusion of the British Socialist party with a number of local Communist organizations. This party is affiliated to the Third or Moscow International. It was gaining adherents in 1921. Its total membership, however, certainly did

not at that date exceed 10,000. Of minor Socialist parties the following deserve mention. The Social Democratic Federation, formerly the National Socialist party, is the result of a split which took place during the war in the British Socialist party. A section of the British Socialist party, including H. M. Hyndman, the veteran Socialist leader, and many of the older members of the earlier Social Democratic Federation, resigned from the British Socialist party as a protest against its anti-war attitude and formed a separate body of their own. The Social Democratic Federation (the name was again assumed at the end of 1920) is affiliated to the Labour party. It is very small, its membership in 1920 being returned as 2,000.

The Fabian Society, founded in 1883-4, has been principally associated with certain intellectual leaders of the right wing of British Socialism, especially Mr. and Mrs. Sidney Webb and Mr. Bernard Shaw. It had about 2,000 members in 1920 and was affiliated to the Labour party. Its pamphlets and other propagandist work exercised a powerful influence on the formation of Socialist opinion during the period from 1889 to 1910, but it has since ceased to count as an effective influence; for, although Mr. and Mrs. Webb and other leaders remained active, they had transferred their main activities to other bodies, such as the Labour party itself.

The Socialist Labour party is an offshoot of the American "De Leonite" Socialist Labour party. It gained considerably in membership and influence during the war, when its leading members took a prominent part in the shop-stewards' movement, and in other rank-and-file trade-union and anti-war movements. Most of its more active members, however, passed over to the Communist party in 1920; and it then ceased to exercise any considerable influence. The Socialist party of Great Britain is a very small and unimportant body of rigid Marxians of the extreme left wing. The National Guilds League, the propagandist organization of the Guild Socialists, is described in the article GUILD SOCIALISM.

It will be seen from the foregoing account that the Socialist movements of the world were in 1921 in a state of unrest and transition, due largely to the events of the war and to the revolutions in Russia. It is impossible to forecast what will be the ultimate result of this ferment of forces and ideas, or in what manner the Socialist parties and societies of the world will eventually regroup themselves. Two clearly defined tendencies can be seen in the movement. The first is a constitutionalist and parliamentary tendency, expressing itself in the activities of the Majority Socialist parties of many countries. Its adherents repudiate for the most part recourse to revolutionary methods save under quite exceptional circumstances. At the other extreme is the tendency represented by Communism and the Communist parties which have arisen in most countries in recent years. Its adherents favour the use of political as well as industrial action, but regard the transition to Socialism essentially in terms of force to be generated by the uprising of the "proletariat." They envisage the transformation of Society by a catastrophic overthrow of the existing political and economic system, and the substitution for it of a new system based on the "dictatorship of the proletariat." Between these two extremes there is no equally definite central body of opinion extending to a number of countries; but in almost every country there are "centrist" groups and tendencies, bearing in some cases a closer resemblance to the constitutionalist right wing (e.g. the Independent Labour party in Great Britain), and in others to the revolutionary left wing (e.g. the Socialist party in Italy).

The Guild Socialists and, in a less degree, the French *Syndicalistes* stand to a considerable extent in a different position, since in their case the main stress is laid neither on revolution nor on constitutional political action, but on the extension of the industrial power of the workers towards control over industry.

A marked feature of the more recent developments of the Socialist movement has been the growing closeness of the relationship between it and the economic organizations created by the workers for the defence of their interests and aspirations as producers and consumers. It has become far more manifest

in the later years of the 19th and the early years of the 20th century that Socialism is not solely, or even mainly, a political movement, but at least equally an industrial movement, aiming at a fundamental transformation not simply in the ownership, but also in the control and administration of industry, and in the motives upon which the industrial system depends. This is, indeed, to some extent a harking back to earlier conceptions of Socialism, such as those of Robert Owen in Great Britain and of Louis Blanc in France. It has resulted in a far closer affiliation between the Socialists of all schools, "right wing," "left wing" and "centre" alike, and the trade-union movement; and the struggles between the rival schools of Socialism now largely reproduce themselves in the industrial sphere, as the various Socialist sections seek to influence the policy and to secure the allegiance of the trade-union organizations. This is true to a less extent of the cooperative movement; but it is becoming increasingly true in this case also.

Based, as it is, mainly upon the organized working-class movement, Socialism has necessarily, to a large extent, an economic basis; but it is important to realize that a great deal of its driving force comes from the fact that it is not only an economic movement, but also a movement based on certain clear and definite ideas which are largely shared by Socialists of all schools.

The differences between Socialists are far more differences as to method than differences as to ideal. Thus all Socialists are agreed that the carrying-on of industry on a basis of private profit produces anti-social results, and that the idea that the interests of the whole are best served by the enlightened pursuit by each private citizen of his own interests is fundamentally wrong. Although they differ widely as to the structure which a Socialist society should assume, and as to the forms of industrial administration which would best express the new community spirit, Socialists are agreed in demanding that all important industries and services should pass over from private hands into some form of social ownership and control, whether into the hands of the State or of local authorities, or of self-governing guilds, or of the cooperative movement, or of other forms of organization designed to express the communal spirit. They are agreed in believing the individual ownership of the means of production, distribution and exchange to be undesirable, and in holding that both the extent and the character of production should be determined, not by any anticipation of individual profit, but by considerations of social need. Moreover, all Socialists insist that with the change from the system of private ownership and control in industry to social ownership and control must go a change in the motives which operate in the industrial system. They hold that, if industries and services are conducted under forms of organization designed in the interests of the whole community, the motive of public service, which is at present thwarted and inhibited by the existence of capitalism, will be brought into play, with the result that the members of the community will be more ready to render willing and efficient service. They are also increasingly of the opinion, first strongly urged by the Guild Socialists, that in order to bring this motive of social service into play it will be essential to democratize the industrial as well as the political system, by providing for a large measure of self-government in industry by the "workers by hand and brain."

The charge used to be brought against the Socialist parties and groups of dwelling almost exclusively upon the economic concerns of Society, and of caring little or nothing for other questions of social and political policy. This charge can hardly be made nowadays; for the Socialist and Labour parties of the world have in almost all cases been led to formulate inclusive programmes and policies, and to take an active part in furthering social reorganization in all spheres of both national and international policy. Perhaps the best exposition of the national and international policy of Socialism of the constitutional type is contained in the pamphlet *Labour and the New Social Order*, issued by the British Labour party in 1918. This pamphlet has had an important international influence. The Communist wing, more preoccupied with questions of revolution

than with plans for reform under the existing system, has not issued any quite comparable declaration of its aims; but the new *Communist Manifesto* of the Third (Moscow) International furnishes the clearest indication of its aims and policy as an international movement.

BOOKS ON SOCIALISM.—A., General.—There is no really good account of Socialism as a whole. The handiest text-books in English are: T. Kirkup, *History of Socialism* (new ed. revised by Edward R. Pease, 1913); and Werner Sombart, *Socialism and the Social Movement* (translated by M. Epstein (1909); R. C. K. Ensor, *Modern Socialism* (1907), is a useful collection of extracts from writings of Socialists of all countries. Max Beer's *History of British Socialism* (2 vols., 1919 and 1920) is indispensable. For the growth of the movement in various countries see Robert Hunter, *Socialists at Work* (1908), and the *Labour International Handbook*, prepared by the Labour Research Department (1921). Of books hostile to Socialism the best known are O. D. Skelton, *Socialism: a Critical Analysis* (1911), and W. H. Mallock, *A Critical Examination of Socialism* (1907); Hartley Withers, *The Case for Capitalism* (1920), may also be consulted. Other useful general books include: E. Bernstein, *Evolutionary Socialism* (1909); Robert Blatchford, *Merric England* (1895); Fabian Society, *Fabian Essays* (1889); J. Bruce Glasier, *The Meaning of Socialism* (1920); Laurence Gronlund, *The Cooperative Commonwealth*, edited by Bernard Shaw (1891); J. Ramsay MacDonald, *Socialism, Critical and Constructive* (1921); William Morris and E. Belfort Bax, *Socialism: its Growth and Outcome* (1893); Bertrand Russell, *Roads to Freedom* (1918); Emile Vandervelde, *Collectivism and Industrial Evolution* (1907); *Le Socialisme contre l'Etat* (1919); W. E. Walling, *Socialism as it is* (1912); H. G. Wells, *New Worlds for Old* (1908, rev. 1914). See also the innumerable pamphlets published by the various Socialist bodies.

B., Marxism.—Karl Marx's *Capital* (English translation, 3 vols. 1887–1909) is, of course, the foundation of most modern Socialist thinking. Of Marx's other works the most important for Socialist theory are: *The Communist Manifesto*, written in collaboration with Friedrich Engels (1847); *The Critique of Political Economy* (English translation, vol. ii. 1907); *The Civil War in France* (1871, reissued 1921); *Revolution and Counter-Revolution or Germany in 1848* (Eng. 1896); *The Poverty of Philosophy* (Eng. 1900). Of the works of Engels the most important are: *Socialism, Utopian and Scientific* (Eng. 1892), and *Landmarks of Scientific Socialism* (Eng. 1907). Karl Kautsky, the leading exponent of political Marxism in Germany, can be best studied in *The Erfurt Program* (Eng. 1910); *The Social Revolution* (Eng. 1902); and in his attack on Bolshevism, *Terrorism and Communism* (Eng. 1920). For the Communist exposition of Marxism see N. Lenin, *The State and Revolution* (Eng. 1919), and other works. Of books on Marx and Marxism the most important are: Max Beer, *The Life and Teaching of Karl Marx* (Eng. 1921); Achille Loria, *Karl Marx* (Eng. 1920), and for a hostile criticism: E. von Böhm-Bawerk, *Karl Marx and the Close of his System* (Eng. 1898). Georges Sorel's *La Décomposition du Marxisme* (1908) and Benedetto Croce's *Historic Materialism and the Economics of Karl Marx* (Eng. 1914) are important detached studies. A much fuller bibliography will be found in *What to Read on Social and Economic Subjects* (Fabian Society, new ed. 1920); and reference should be made to the bibliographies at the end of the articles on COMMUNISM, GUILD SOCIALISM, SYNDICALISM. There is, of course, a very large literature of the subject in almost every European language.

(G. D. H. C.)

SODEN, HERMANN, FREIHERR VON (1852–1914), German biblical scholar (see 25.339), died Jan. 15 1914.

SOLDENE, EMILY (1840–1912), English singer and actress, was born at Islington, London, in 1840. She had made her debut in 1864 on the concert stage, and in 1871 appeared in *Genevieve de Brabant*, her favourite rôle, and in *La Fille de Madame Angot* in 1872. Her successes were mainly in opera-bouffe, and she retired young from the stage. She published one novel, *Young Mrs. Staples* (1896), and *My Theatrical and Musical Recollections* (1897). She died in London April 8 1912.

SOLF, WILHELM (1862–), German colonial politician, and, at the time of the revolution, Secretary of State for Foreign Affairs, was born Oct. 5 1862 in Berlin. He made a special study of Sanskrit and Oriental languages, and, after a long sojourn at Calcutta, returned to Germany in order to study political science. He then entered the German Colonial Service and, after having been employed in a judicial post in German East Africa, was sent to Samoa, first as president of the municipal council (1899) at Apia under the old "condominium" of Great Britain, Germany and America and afterwards as governor of German Samoa (1900). In 1911 he was appointed German colonial secretary and achieved considerable success in the reform of the German colonial administration. When Prince Max of Baden's Ministry

of desperation was formed towards the end of the World War, Solf was appointed Secretary of State for Foreign Affairs on Oct. 3 1918. In this capacity it fell to his lot to conduct the negotiations for the Armistice, first with President Wilson and then with the Allied and Associated Powers. He continued to hold this office as an "expert" under the revolutionary Socialist Government of the Commissioners of the People, and did not resign till Dec. 17 1918. In 1920 he was appointed German chargé d'affaires and afterwards ambassador to Tokio. He was the author of *Weltpolitik und Kolonialpolitik* (1918) and of *Kolonialpolitik, Mein politisches Vermächtniss* (1919).

SOMALILAND (see 25,378).—The territorial division of Somaliland between Abyssinia, Great Britain, France and Italy, except for a comparatively slight readjustment of the Italo-Abyssinian frontier, remained unchanged during the period 1910-21. However, Italy obtained from Great Britain the promise of the addition to Italian Somaliland of part of the Jubaland province of British East Africa (Kenya Colony). Italy also desired to acquire the port of Jibuti (French Somaliland), but failed to do so (see AFRICA: History).

BRITISH SOMALILAND.—From 1910 to 1920 the mullah Mahammed bin Abdullah, popularly known in Britain as the "Mad Mullah," continued to dominate the interior of the protectorate. In March 1910 the British troops were withdrawn to the seaports and a policy of "strict coastal concentration" adopted. Officially arrangements had been made to enable the friendly tribes to defend themselves from attack by the Mullah; in fact the "friendlies" were not only systematically raided by the dervishes, but also quarrelled among themselves. At the end of 1912 a camel constabulary, 150 strong, was raised and under R. C. Corfield checked inter-tribal fighting. In Aug. 1913 Corfield, acting against instructions, engaged a raiding party of some 200 dervishes at a place called Dolmadoba, 110 m. S.E. of Berbera. In the action Corfield was killed, his little force of 100 men had over 50% casualties and was compelled to fall back. G. F. Archer, the acting commissioner, rode out from Burao (40 m. distant) with an escort of 20 Indian troops and covered the retreat. The dervishes proceeded to occupy some of the chief grazing ground of the "friendlies" and the Mullah built strong forts at Jidballi and Shimber Berris—places in the S.E. part of the British protectorate, Jidballi being 220 m. S.E. of Berbera. In March 1914 dervish raiders reached the coast and fired into the town of Berbera. Archer, who in May 1914 became commissioner of the protectorate¹ in succession to H. A. Byatt, urged that duty should compel Britain to safeguard the tribes in the protectorate and further operations were authorized. Sheikh and Burao were reoccupied and on Nov. 23 Maj. (local Lt.-Col.) T. A. Cubitt defeated the dervishes at Shimber Berris. Cubitt having returned to Burao, the dervishes reoccupied Shimber Berris. Here they were again attacked by Cubitt on Feb. 3-4 1915, and after severe fighting, partly in caves, were driven out and all their forts destroyed. There was no means of following up the Mullah, nor any belief that his power had been crushed, though for over a year after the destruction of Shimber Berris he remained quiescent. His headquarters were at Tale, towards the Italian frontier, where, under the direction of Arab masous from the Yemen, his followers built elaborate stone fortifications of great strength.

Subsequently the Mullah again overran the centre and east of the protectorate, building more forts and making many raids on the "friendlies." This state of affairs lasted until 1920, when carefully planned and ably executed operations resulted in the complete destruction of the Mullah's forces. The Mullah had, in Sept. 1919, suddenly moved northward from Tale to Jidballi with most of his fighting men, establishing his own camp in the hills at Medishe, 12 m. N.W. of Jidballi. This move, occasioned by the hostility of the Mijertin Somalis, proved advantageous to the British plans. The main attack was made from the air, the force employed being one flight of DH9 aeroplanes under Group-Capt. R. Gordon. The ground troops were a King's African Rifles contingent (700 rifles), the Somaliland Camel Corps (700 rifles) and the 1st 101st Grenadiers, Indian

¹ In Oct. 1919 the title was changed to that of governor.

Army (400 rifles). Lt.-Col. G. H. Summers was in command, the whole operations being, apart from the initial attacks by the air force, under the personal direction of Archer. Hostilities began on Jan. 21 with an aerial attack on the Mullah's camp at Medishe and ended on Feb. 12 with the flight of the Mullah, his eldest son, a brother and four or five followers. The rest of his followers were killed or captured, together with all his stock and property of every kind. The killed included 7 of the Mullah's sons; the captured, his 5 wives, 6 of his sons, 4 daughters and 2 sisters. The British casualties were very slight—3 natives killed and 8 wounded. The cost of these operations was about £84,000. Their success was primarily and mainly due to the Royal Air Force. The dervishes, good fighting men, were demoralized from the start by the attacks from the air and offered no serious opposition. They appeared not to know the character of aeroplanes; when the first attack was made on Medishe the Mullah is reported to have regarded the appearance of the machines in the air as a divine manifestation. It is known that on their approach he collected his people around him and awaited their coming under the white canopy used on state occasions. The first bomb killed an uncle of the Mullah's, who was standing by his side, and singed the Mullah's clothing.

When the British captured Tale (Feb. 9) the Mullah was already in flight, and he succeeded in eluding pursuit with the small following named. He crossed the Haudh to Galadi. News was received in the summer of 1921 that the Mullah had died at Imi in the heart of the Ogaden country the previous Feb., deserted and destitute. The Mullah's defeat was regarded in Somaliland as marking the deliverance of the country from 21 years of dervish oppression. Archer, to whose persistent advocacy this result was due, was created a K.C.M.G.

The World War and the high prices prevailing in 1918-20 had a marked influence on trade, the Somalis exporting large numbers of sheep and goats for the Aden Field Force and many thousands of camels for the Egyptian Expeditionary Force. Apart from this the most valuable export was skins and hides, the Somali skins being of very high quality. The great majority of the skins, especially the sheepskins, went eventually to the American market. The chief imports—American grey sheeting, dates, rice, sugar and tea—showed a heavy decline in quantity during the war, but an increase in value. Trade with Abyssinia continued, but the Zeila route could not compete beyond Harrar with the railway-borne traffic through Jibuti. In 1910-1 the total value of imports was £267,000 and of exports £247,000. In 1919-20 the figures were: imports £754,000, exports £346,000 (of which £134,000 was the value of hides). External trade was mainly in the hands of Indians and Arabs.

Revenue was mainly derived from customs and was inadequate to meet the cost of administration. The figures for 1910-1 were: revenue £30,000, expenditure £99,000; for 1919-20 revenue £81,000, expenditure £322,000. Deficits, incurred mainly for military purposes, were met by Imperial grants in aid. There was evidence to show that, with internal peace and a reasonable development of the resources of the country, the protectorate would become self-supporting. It was known to contain oil-fields, favourably reported upon by experts as long ago as 1914. A step towards opening the interior was taken in 1920 when a motor road was made from Berbera (the capital and chief port) to Lower Sheikh and from Upper Sheikh to Burao.

See R. E. Drake Brockman, *British Somaliland* (1917); H. F. Prevost Battersby, *Richard Corfield of Somaliland* (1914); A. H. E. Morse, *My Somali Book* (1913); A. Hamilton, *Somaliland* (1911); and the annual Colonial Office reports on the protectorate. The account of the final overthrow of the Mullah is given in a supplement to the *London Gazette* of Nov. 1 1920.

FRENCH SOMALILAND.—Situated on the western shores of the Bab-el-Mandeb, French Somaliland is important as possessing the only French port on the Suez Canal route and as being the main artery of trade with Abyssinia. The pop. in 1917 was estimated at 206,000. Jibuti, the port and capital, had 13,608 inhabitants, of whom 294 were Europeans (107 French).

The resources of the country, which is largely arid, are limited. Date palms have been planted in the desert round Jibuti. Cotton-growing was tried in the same neighbourhood but was abandoned. On the higher ground there is rich grassland, on which the natives—Somali and Danakil—have herds of camels, goats and black-faced sheep. The Bahr 'Asal has been exploited since 1912 for its immense deposits of salt; in 1918 the export was 11,500 metric tons. There is also a considerable fishing industry, and mother-of-pearl figures among the exports.

Jibuti is regularly visited by French, British and Italian steamers and has a local service to Aden. In 1917 the steamers entered at

Jibuti numbered 272, with a tonnage of 643,000. About 90 % of its trade is the transit of goods to and from Abyssinia, the railway from Jibuti to Addis Ababa being owned by a French company. In 1913, before the railway had reached Addis Ababa, the value of the transit trade was £1,636,000. In 1918, with the railway completed, the imports destined for Abyssinia were valued at £1,433,000 and the exports from Abyssinia at £2,622,000. There is also a trade in supplying passing ships with coal, previously imported. Textiles, food-stuffs and coal are the chief imports; the exports are the characteristic produce of Abyssinia—coffee, live stock, hides and skins, ivory, rubber, beeswax, etc.

The colony is administered by a governor assisted by a council composed equally of official and non-official members. The budget for 1919 was balanced at 2,370,000 francs. Relations between the Somali and Danakil and the French proved satisfactory, the tribes being very lightly administered. A small military force was maintained for the security of Jibuti and the railway. The colony was on good relations with its Italian, British and Abyssinian neighbours, save for differences with the Abyssinian customs officials, whose valuation of dutiable goods passing inwards was often arbitrary. Some anxiety was caused in 1917-8 by the presence of Lij Yasu, the deposed Emperor of Abyssinia, in the Danakil country, and by his threats to the railway. His effort to raise the tribes against the French failed.

See the *Côte Française des Somalis* (annual reports by the French Colonial Ministry), and *L'Afrique Française* (monthly).

ITALIAN SOMALILAND.—The efforts of Italy in Somaliland during 1910-21 were concentrated upon the southern part of their protectorate. By a royal decree of July 1910 this southern region, Benadir and its hinterland, was constituted a Crown colony, administered by a civil governor resident at Mukdishu (*Ital.* Mogadiscio), and divided into four "commissariats." This region included the fertile valleys of the lower Juba and Webi Shebelle and the good grazing land on the plateau between those rivers. Dura was the main crop, but cotton and rice plantations were formed along the Juba and aid given to Italian colonization companies. The result was not great; the Somalis preferred a nomadic life, while the agricultural classes, negroes or semi-negroes, were few in number. This paucity of labour was the most serious problem confronting the administration.

By the occupation of strategic posts and the building of roads the Italians secured the safety of Benadir, and with this security a considerable trade developed with Abyssinia, chiefly via Lugh, on the Juba. But the absence of any harbours—all the ports are open roadsteads—proved a great drawback, and to remedy this difficulty Italy had obtained facilities at the harbour of Kismayu, in British East Africa (Kenya), some little distance south of the mouth of the Juba. That river formed the Anglo-Italian frontier. On Dec. 24 1915 an agreement was reached for the appointment of a permanent mixed commission to deal with customs, transit, conservancy, navigation, irrigation and other purposes in the Juba region. Italian desires in respect to the Juba were, however, of a wider character. It was believed that with complete control of the lower Juba—spoken of as a second Nile—the economic future of the colony would be assured, and in the treaty with the Allies which preceded her entry into the World War Italy secured *inter alia* a promise of the rectification of her Somaliland frontier. Formal negotiations to that end were entered upon in 1919, when Great Britain agreed to the cession of Kismayu and of a strip of land which would give Italy both banks of the Juba.

The northern part of Italian Somaliland remained under the rule of Somali chiefs, of whom the most important was the Sultan of the Mijertins, whose territory included the coast facing the Gulf of Aden. The Mijertins, who number approximately 100,000, possess large numbers of camels, sheep and cattle, and their country, as also Obbia and the Nogal territory, abounds in plants which furnish gum-arabic, myrrh, frankincense, etc. The Mijertins were near neighbours of Mohammed bin Abdullah, the "Mad Mullah," who between 1905 and 1909 was settled in the lower Nogal region. The hostility of the Mijertins finally drove out the Mullah, who established himself at Tale, in the northeast corner of British Somaliland. The continued and unwelcome attentions of the Mijertins induced the Mullah in 1919 to remove farther into the British protectorate, while in 1920 the Mijertin Sultan, Osman Mahmoud, assembled his warriors to prevent the Mullah's reentry into Italian territory.

Italian relations with Abyssinia were satisfactory. Following the Italo-Abyssinian convention of 1908 the frontier was delimited in 1911, tribal boundaries rather than physical features determining the line chosen. In the north, where the frontier reaches the southern limits of British Somaliland, the Italo-Abyssinian frontier was fixed at 48° E., instead of 47° E., as provided in the 1908 agreement. This gave to Abyssinia the small portion of Ogaden tribal lands which had been in the Italian protectorate, including Galadi.

The external trade, valued at £174,000 in 1908-9, had risen to £326,000 in 1912-3, and was £800,000 in 1918. Throughout this period imports greatly exceeded exports, the exports in 1918 for example being valued at £243,000 only. Imports are chiefly cotton goods from Italy and food-stuffs. Skins form, in value, 75 % of the exports. The expenses of administration exceed revenue; the Italian grant in aid (£119,000 in 1910-1) was £186,000 in 1920-1, when the budget was balanced at £440,000. Of the expenditure one-fifth was for the military force, some 3,000 strong, sent from Eritrea, the men being Abyssinians.

A 1920 estimate put the total pop. as high as 650,000. Mukdishu had 14,000 inhabitants. Besides a few hundred Europeans there are at the coast towns settlements of Arab and Indian traders. Mukdishu was, in 1915, connected with Massawa by a high-power wireless station. Surveys for railways had been made, but no construction had begun up to 1921. There were in that year some 1,500 m. of road in southern Somaliland.

See G. de Martino (sometime governor of the colony), *La Somalia Nostra* (1913), and *Italian Somaliland*, a British Foreign Office handbook, with bibliography (1920). (F. R. C.)

SOMERSET, ISABELLA CAROLINE [LADY HENRY SOMERSET] (1851-1921), English philanthropist, was born in London Aug. 3 1851, the eldest daughter and co-heiress of the 3rd and last Earl Somers. She married in 1873 Lord Henry Somerset, son of the 8th Duke of Beaufort, at one time comptroller of Queen Victoria's household, from whom she later separated. She became well known as a temperance reformer and interested herself deeply in the reclamation of inebriate women, with this end in view founding the Duxhurst Farm Colony, near Reigate, the first settlement of the kind in England. In connexion with it she established a home for destitute children and a "children's village" for saving infant life. Lady Henry Somerset was for many years president of the National British Women's Temperance Association, and made a reputation as an able speaker. In 1894 she founded the *Woman's Signal* in the interests of women's work, becoming its editor, and she was also the author of various children's books and many pamphlets and articles on social work. She died in London March 12 1921.

SOMME, BATTLES OF THE.—Under this heading it is proposed to deal with the principal battles which took place in Picardy and southern Artois during the World War. The geographical limits in which these battles took place may be roughly defined as the Scarpe on the N., the Oise on the S., the line Cambrai-La Fère on the E., and the line Amiens-Creil on the W.

The strategic geography of this region is governed by the course of the Somme between St. Quentin and Amiens; in the upper part of this course it runs S.-N., in the lower E.-W., and in that general course it continues to the sea. Thus from Péronne, the point at which the river bends through the right angle, to Abbeville, a water barrier divides opposed armies that face N.-S., and separates each into well-defined tactical theatres if they are operating towards the E. and the W. The upper (or strictly the middle) Somme (Péronne-Ham) prolonged to the Oise by the Crozat Canal, on the other hand separates the E.-W. adversaries and either protects or hampers those operating in N.-S. direction. Thus the operations which took place in the region, profoundly influenced by the alignment of the Somme and its tributaries, are in spite of their dissimilarity, properly designated "battles of the Somme."

In the first phase of the war, this region was traversed by the German I. Army, and a number of local combats took place between it and the forces that Joffre gathered, little by little, to form his VI. Army and outflank the Germans in their wheel.

More severe and continuous fighting took place between the Oise and the Scarpe during the development of the opposed northern wings in the "Race to the Sea."

Of this the battles of Lassigny, Roye, and Albert, which led up to and even into, the battle of Arras (*see* ARTOIS, BATTLES IN) formed the first phase.

In each locality or area the effort of each side to hold the other frontally, while outflanking him to the N., produced an ever-extending frontal battle that, after see-sawing to and fro, produced the line of stabilization characteristic of the trench warfare period.

In 1915 the line of stabilization between the Oise and the Scarpe was relatively quiet. And apart from a combat in Jan. 1916, in which the French lost possession of Frise, the line, as it was left at the close of the "Race to the Sea" in 1914, was the starting line of the great offensive of July 1 1916.

I. BATTLES OF JULY-NOVEMBER 1916

The four months and a half of almost continuous fighting which began with the great attack of July 1 1916 mark a turning-point in the World War in more than one respect. With July 1 1916 began that period of sustained and systematic Allied pressure upon the enemy which, though interrupted in the spring and early summer of 1918 by the desperate German counter-offensive, in the end wore his resistance down. Before July 1916 the Allied offensives had been relatively brief interludes in a long period of stalemate; from that date onwards it was the periods when active operations were in abeyance which formed the interludes. Further it is clear even from the grudging admissions of the German commanders that this great struggle materially affected the strategical situation as no earlier Allied offensive had, that the strain which the maintenance of their defence imposed on the resources and the *moral* of the German armies exercised an important influence on the course of the struggle. The actual gains of ground made by the Allies between July 1-Nov. 19 1916 were not large, but in making them they established a moral ascendancy over their enemy and brought home to the Germans the probability of defeat. And in this struggle the British army had for the first time to bear the major part: the French who fought on Sir Douglas Haig's right with so much gallantry and efficiency played a part of the greatest importance in the battle, but one as distinctly subordinate to the efforts of the British as the British attacks in May and Sept. 1915 had been to those of the French.

To speak, as is the common habit, of "the battle of the Somme" in 1916 is to fall into a natural but serious error. The operations were a series of great battles, each surpassing all those of previous wars in magnitude and intensity, parts of a common whole but still definite and separate operations for distinct purposes. It is possible to distinguish four main phases in the operations: first the winning of a position on the southern edge of the main plateau between the Somme and the Ancre, a matter of three weeks' hard fighting, embracing two attacks on a large scale and many lesser intermediate operations; in the second phase, which lasted till the middle of Sept., nearly two months, the operation took the shape of a septe for this main ridge and for the extension of the footing which the Allies had gained upon it so as to enable them to develop their offensive on both flanks as well as straight to their front; in the third phase the Allies pushed forward across the ridge and down its farther side, only to have their progress arrested by the persistent bad weather which set in about the beginning of Oct. and prevented anything like a general attack upon the rearward system of defences which covered Bapaume and Péronne; the fourth phase of the operations, extending from the beginning of Oct. till Nov. 18, saw a series of smaller efforts against particular points and strongholds, culminating in a bigger attack on Nov. 13 astride the Ancre which completed the reduction of the main ridge and captured ground of vital importance on the right bank of the Ancre. But the main rearward system was not penetrated, thanks largely to the mud which hampered every movement of the attackers and made the performance of the normal adminis-

trative services for the troops in the advanced position a task of the greatest difficulty. The devastating effects of the repeated bombardments made themselves felt over the whole area: houses and whole villages were reduced to ruins; woods were represented by a few shattered stumps and a tangle of broken trunks and branches; roads were rendered impassable till the battlefield became a dreary wilderness of mud and water-logged shell craters. To maintain trenches in defensible condition was all but impossible, to consolidate a captured position, difficult even in dry weather, became practically out of the question. The middle of Nov., therefore, saw active operations broken off and two months elapsed before anything more than quite minor operations became possible. The operations during the two months which preceded the German withdrawal to the Hindenburg line, including as they did a systematic advance up both banks of the Ancre on Bapaume, were essentially the continuation and completion of those of the last phase of the operations of the autumn, and it would be not unreasonable to treat them as yet another stage of "the Somme." They had brought the British practically within striking distance of the last line which covered Bapaume and Péronne when in the middle of March the German retreat anticipated its enforced evacuation.

First Phase.—The German positions astride the Somme and Ancre attacked on July 1 1916 were strong by nature and had been made doubly formidable by every device known to the military engineer. Their line represented the positions taken up in Oct. 1914 by the German VI. Army in the course of that "Race to the Sea" which culminated in the desperate fighting of Oct. and Nov. 1914 for Ypres and the Yser. The line then established had remained substantially unchanged, for neither side had since then attempted any operations of importance in this quarter where the British III. Army had relieved the French in front of Albert in July 1915. Hence the Germans had had ample time to develop their defences to the highest degree: villages and woods had become fortresses; two elaborate trench systems, each comprising several lines, had been dug, the second from two to three miles in rear of the first, "switches"—communication trenches—connected them up and greatly complicated the task of the attacker who should happen to penetrate any part of the front. Deep dug-outs, to the construction of which the chalk country lent itself admirably, gave shelter to the trench garrisons during bombardments; deep belts of barbed wire protected the different trenches, and most careful and skillful arrangements had been made for enfilade and supporting fire from numerous machine-guns; positions of special tactical value had been secured by formidable redoubts, while a well-placed and ample artillery was ready to support the defenders. Moreover, the advantage of the ground lay with the Germans, whose facilities for observation were excellent.

The frontage selected for the attack extended from just N. of Lihons on the extreme right to the Somme at Curlu, a distance of about nine miles, crossed the Somme and ran as before from N. and S. to Maricourt, another 3,000 yards. Here the French front ended, and the line turned sharply and ran W. for 7,000 yards. Here it turned N. again, making a sharp salient at the village of Pricourt. Thence to the Ancre, approximately 10,000 yards, the line ran over several spurs which jut S.W. from the ridge which formed the backbone of the German position. This ridge runs roughly N.W. from Péronne, dividing the valley of the Somme from the basins of the Scarpe and Scheldt. After crossing the Ancre the German line continued in a generally N. direction in front of Beaumont-Hamel and Serre, this last village forming the N. end of the front to be attacked, though a couple of miles farther N. a subsidiary attack was to be made against the pronounced salient at Gommecourt. The total frontage was over 25 miles, exclusive of the Gommecourt operations.

Against this frontage the British had available the five army corps of Sir Henry Rawlinson's IV. Army, which put into the front line eleven divisions keeping another nine in reserve, while two divisions of the III. Army (Sir E. Allenby) were to be employed against Gommecourt. On the German side some six divisions were holding the line to be attacked by the British.

Opposite the French, where they do not appear to have been expecting an attack, they were proportionately weaker, having three divisions in the line on a front of eleven miles.

Relatively to the numbers engaged in the Loos offensive, the British army was not employing in its first attack any greatly increased force of infantry. Where its preparations had altogether outstripped those of Sept. 1915 was in artillery, and it was on this arm that its chief hopes rested. For the six days' preliminary bombardment the heavy guns available were so numerous that it was difficult to find good positions for them all. Indeed the artillery personnel engaged in the first attack came to nearly half that of the infantry, and in weight as well as in number of guns the Allied artillery were able to establish a predominance over the enemy. This was largely due to the success with which the Royal Flying Corps was at the time contending against the enemy's aircraft; the mastery of the air which it had established ensured to the Allies—when weather conditions permitted—observation of artillery fire and denied to the enemy this important advantage and the opportunity of gaining information of movements behind the lines. Ammunition, too, if not as unlimited as it was to be in 1918, was plentiful. The careful economy which had been a painful necessity during the winter and spring had allowed the accumulation of large reserves, and although the great development of munition-making in England, undertaken in the summer of 1915, was only just beginning to produce its effects, its influence was already apparent in the effective bombardment to which the German positions were subjected for the week preceding the attack.

In one way the bombardment was almost too effective. The destruction was in some places so complete that it proved far more difficult to consolidate captured positions and to hold them against counter-attacks than to carry them. But to a large extent the German defences proved capable of withstanding even the tremendous shelling to which they had been subjected. Many nests of machine-guns had escaped intact, in places there were still stretches of uncut wire and the German artillery were able to make a most effective reply. North of the Ancre in particular German counter-battery work had much to do with the failure of the 31st Div. (VIII. Corps), the left of the main attack, to capture Serre. On its right the 4th Div. penetrated some way into the German position N. of Beaumont-Hamel, but found its flanks exposed by the check to the 31st Div. and by the failure of the 20th Div. against Beaumont-Hamel itself, one of the very strongest parts of the German line. It was counter-attacked and driven out after a stubborn resistance.

Immediately S. of the Ancre the X. Corps fared little better than the VIII. Its left division, the 36th (Ulster) began well and pressed forward N. of Thiépval. But Thiépval itself, another formidable fortress, defied the attacks of the 40th and 32nd Divs., with the result that the very success of the 36th contributed to its undoing. Its advanced detachments were cut off and overwhelmed, and in the end it was forced to evacuate its captures. South of Thiépval, however, at the angle known as the Leipzig Salient a slender foothold was gained and maintained despite the vigour of the German counter-attacks. On the right of the X. Corps, the 8th and 34th Divs. of the III. Corps had two very difficult places to attack in the strongly fortified villages of Ovillers and La Boisselle. Neither of these was captured, but the III. Corps managed to penetrate the German lines on either side of them, very slightly N. of Ovillers, rather more deeply between that and La Boisselle, and very much deeper S. of La Boisselle. Here also the 21st Div. of the XV. Corps, flanked on its right by a brigade of the 17th Div., made substantial progress N. of Fricourt, which village was in danger of being cut off, as E. of it the 7th Div., also of the XV. Corps, was most successful, storming the German front lines and penetrating as far as the village of Mametz. To the right again the XIII. Corps (18th and 30th Divs.) made great progress, reaching all its objectives from Montauban, W. to Mametz and E. to the Briquerie. Thus, despite the failure of the British left and the limited success of the centre, the right had made a promising opening.

The reverse on the left may be in part explained by the excep-

tional strength of the German defences N. of the Ancre, and by the concentration of the German artillery in that quarter where they both expected and especially feared an attack. Had Beaumont-Hamel and Thiépval gone the German position on the main ridge would have been more seriously endangered than it was by the British success between Fricourt and Montauban. But if the Germans were less well prepared for an attack on this frontage, opposite the French they were certainly neither expecting one nor ready for it; and this, together with the ample artillery support available and the superior experience of the French gunners, contributed to the complete success of General Foch's attack. On both banks of the Somme his infantry mastered the German front system and made their way deep into their positions, reaching the outskirts of Hardecourt and Curlu N. of the river, while S. of it they progressed even farther, taking Dompierre and Foy. Exploiting their victory, the French pressed on, and by July 4 not only penetrated into the second system of German defences, but captured it over a length of six miles from Estrées N. to the Somme at Buscourt. Some 6,000 prisoners fell into their hands, with many guns, and as S. of the river they were well forward of the line reached on the right bank they were able to enfilade the German positions from across the river.

While General Foch's troops were exploiting and increasing their gains the British IV. Army was similarly employed, though on a frontage shorter than that originally attacked. Recognizing the futility of renewing the attempt on the formidable positions astride the Ancre, Sir Douglas Haig decided to concentrate his efforts on pushing home the success of his right. Divisions which had lost particularly heavily, like the 8th and 36th, were withdrawn and replaced by others from the reserves. Four days of hard and continuous fighting substantially extended the lodgment gained on July 1. The 7th and 17th Divs. joined hands behind Fricourt, cutting off that village; then, supported by the 23rd, they pressed forward against Contalmaison while the 10th Div. on their left reduced La Boisselle and made headway towards Ovillers. Advancing from Montauban after repulsing several strong counter-attacks the XIII. Corps captured Caterpillar and Bernafay Woods. With this the hostile front system over a front of six miles was secured and consolidated, but before a footing could be gained on the main ridge it was necessary to cross the valley which runs N.E. from Fricourt, to gain more ground towards Contalmaison, and to reduce Ovillers.

On July 7 therefore a second stage of the first battle started. the 12th and 25th Divs. assailing Ovillers while the troops who had cleared Fricourt and La Boisselle pushed on against Contalmaison and the 38th (Welsh) Div. attacked Mametz Wood. This last proved difficult to reduce but was finally cleared by the 21st Division. By July 13 Contalmaison also had been taken, and after some desperate fighting by the 9th, 18th, and 30th Divs. important gains had been made on the British right, Trones Wood (which changed hands repeatedly) being the scene of the fiercest contests. Meanwhile the French had cleared Hardecourt and advanced their line S. of the Somme to Biaches.

During all this fighting the German resistance had been stiffening. The stubborn fights which had been put up for Ovillers and Contalmaison and Trones Wood had given time for the arrival of strong reinforcements and the reorganization of the defence. The divisions on whom had fallen the brunt of the bombardment and of the first attack had been relieved by fresher troops; artillery had been shifted to meet the requirements of the new situation. Moreover, as the Allies advanced over the area devastated by the bombardment their administrative difficulties increased at each step; the advance of the guns to new positions meant new arrangements for ammunition supply, roads had to be repaired or improvised, and the feeding and watering of the advanced troops were laborious and troublesome. All these circumstances added to the difficulties of the next step, the assault upon the enemy's second system of defences on the S. crest of the main ridge. This system, though hardly as strong as that stormed on July 1, was formidable enough, and, like it, was supported by the fortified villages Longueval, Bazentin le Grand, and Bazentin le Petit and by several woods. To get within assaulting distance

More severe and continuous fighting took place between the Oise and the Scarpe during the development of the opposed northern wings in the "Race to the Sea."

Of this the battles of Lassigny, Roye, and Albert, which led up to and even into, the battle of Arras (*see* ARTOIS, BATTLES IN) formed the first phase.

In each locality or area the effort of each side to hold the other frontally, while outflanking him to the N., produced an ever-extending frontal battle that, after see-sawing to and fro, produced the line of stabilization characteristic of the trench warfare period.

In 1915 the line of stabilization between the Oise and the Scarpe was relatively quiet. And apart from a combat in Jan. 1916, in which the French lost possession of Frise, the line, as it was left at the close of the "Race to the Sea" in 1914, was the starting line of the great offensive of July 1 1916.

I. BATTLES OF JULY-NOVEMBER 1916

The four months and a half of almost continuous fighting which began with the great attack of July 1 1916 mark a turning-point in the World War in more than one respect. With July 1 1916 began that period of sustained and systematic Allied pressure upon the enemy which, though interrupted in the spring and early summer of 1918 by the desperate German counter-offensive, in the end wore his resistance down. Before July 1916 the Allied offensives had been relatively brief interludes in a long period of stalemate; from that date onwards it was the periods when active operations were in abeyance which formed the interludes. Further it is clear even from the grudging admissions of the German commanders that this great struggle materially affected the strategical situation as no earlier Allied offensive had, that the strain which the maintenance of their defence imposed on the resources and the *moral* of the German armies exercised an important influence on the course of the struggle. The actual gains of ground made by the Allies between July 1-Nov. 19 1916 were not large, but in making them they established a moral ascendancy over their enemy and brought home to the Germans the probability of defeat. And in this struggle the British army had for the first time to bear the major part: the French who fought on Sir Douglas Haig's right with so much gallantry and efficiency played a part of the greatest importance in the battle, but one as distinctly subordinate to the efforts of the British as the British attacks in May and Sept. 1915 had been to those of the French.

To speak, as is the common habit, of "the battle of the Somme" in 1916 is to fall into a natural but serious error. The operations were a series of great battles, each surpassing all those of previous wars in magnitude and intensity, parts of a common whole but still definite and separate operations for distinct purposes. It is possible to distinguish four main phases in the operations: first the winning of a position on the southern edge of the main plateau between the Somme and the Ancre, a matter of three weeks' hard fighting, embracing two attacks on a large scale and many lesser intermediate operations; in the second phase, which lasted till the middle of Sept., nearly two months, the operation took the shape of a septe for this main ridge and for the extension of the footing which the Allies had gained upon it so as to enable them to develop their offensive on both flanks as well as straight to their front; in the third phase the Allies pushed forward across the ridge and down its farther side, only to have their progress arrested by the persistent bad weather which set in about the beginning of Oct. and prevented anything like a general attack upon the rearward system of defences which covered Bapaume and Péronne; the fourth phase of the operations, extending from the beginning of Oct. till Nov. 18, saw a series of smaller efforts against particular points and strongholds, culminating in a bigger attack on Nov. 13 astride the Ancre which completed the reduction of the main ridge and captured ground of vital importance on the right bank of the Ancre. But the main rearward system was not penetrated, thanks largely to the mud which hampered every movement of the attackers and made the performance of the normal adminis-

trative services for the troops in the advanced position a task of the greatest difficulty. The devastating effects of the repeated bombardments made themselves felt over the whole area: houses and whole villages were reduced to ruins; woods were represented by a few shattered stumps and a tangle of broken trunks and branches; roads were rendered impassable till the battlefield became a dreary wilderness of mud and water-logged shell craters. To maintain trenches in defensible condition was all but impossible, to consolidate a captured position, difficult even in dry weather, became practically out of the question. The middle of Nov., therefore, saw active operations broken off and two months elapsed before anything more than quite minor operations became possible. The operations during the two months which preceded the German withdrawal to the Hindenburg line, including as they did a systematic advance up both banks of the Ancre on Bapaume, were essentially the continuation and completion of those of the last phase of the operations of the autumn, and it would be not unreasonable to treat them as yet another stage of "the Somme." They had brought the British practically within striking distance of the last line which covered Bapaume and Péronne when in the middle of March the German retreat anticipated its enforced evacuation.

First Phase.—The German positions astride the Somme and Ancre attacked on July 1 1916 were strong by nature and had been made doubly formidable by every device known to the military engineer. Their line represented the positions taken up in Oct. 1914 by the German VI. Army in the course of that "Race to the Sea" which culminated in the desperate fighting of Oct. and Nov. 1914 for Ypres and the Yser. The line then established had remained substantially unchanged, for neither side had since then attempted any operations of importance in this quarter where the British III. Army had relieved the French in front of Albert in July 1915. Hence the Germans had had ample time to develop their defences to the highest degree: villages and woods had become fortresses; two elaborate trench systems, each comprising several lines, had been dug, the second from two to three miles in rear of the first, "switches"—communication trenches—connected them up and greatly complicated the task of the attacker who should happen to penetrate any part of the front. Deep dug-outs, to the construction of which the chalk country lent itself admirably, gave shelter to the trench garrisons during bombardments; deep belts of barbed wire protected the different trenches, and most careful and skillful arrangements had been made for enfilade and supporting fire from numerous machine-guns; positions of special tactical value had been secured by formidable redoubts, while a well-placed and ample artillery was ready to support the defenders. Moreover, the advantage of the ground lay with the Germans, whose facilities for observation were excellent.

The frontage selected for the attack extended from just N. of Lihons on the extreme right to the Somme at Curlu, a distance of about nine miles, crossed the Somme and ran as before from N. and S. to Maricourt, another 3,000 yards. Here the French front ended, and the line turned sharply and ran W. for 7,000 yards. Here it turned N. again, making a sharp salient at the village of Pricourt. Thence to the Ancre, approximately 10,000 yards, the line ran over several spurs which jut S.W. from the ridge which formed the backbone of the German position. This ridge runs roughly N.W. from Péronne, dividing the valley of the Somme from the basins of the Scarpe and Scheldt. After crossing the Ancre the German line continued in a generally N. direction in front of Beaumont-Hamel and Serre, this last village forming the N. end of the front to be attacked, though a couple of miles farther N. a subsidiary attack was to be made against the pronounced salient at Gommecourt. The total frontage was over 25 miles, exclusive of the Gommecourt operations.

Against this frontage the British had available the five army corps of Sir Henry Rawlinson's IV. Army, which put into the front line eleven divisions keeping another nine in reserve, while two divisions of the III. Army (Sir E. Allenby) were to be employed against Gommecourt. On the German side some six divisions were holding the line to be attacked by the British.

SOMME, BATTLES OF THE

and though in the British centre between High Wood and Delville Wood ground was gained, German counter-attacks recovered most of it. But the right fared better. The 20th (Light) Div., assisted by a brigade of the 16th (Irish) Div., at last mastered Guillemont, the obstacle which had held up so many attacks and cost so many casualties. The 7th Div. reached Ginchy, but after desperate fighting was thrust out of it again, while on the extreme right three days of hard fighting gave the 5th Div. Falfemont Farm and brought it to Leuze Wood. Here, therefore, the original German second system, which had so long held back the British right, was at last pierced and when on Sept. 9 this success was followed up by the capture and retention of Ginchy by the 16th Div. and the advance of the 56th (London) Div. up to Bouleaux Wood, the great stumbling-block to the advance of the British centre was at last so far removed that it could now push forward without putting itself at a grave disadvantage from enfilade and reverse fire. Thus the battles for Guillemont and Ginchy (Sept. 3 and 9) mark a very definite stage in the Allied progress. The forward crest of the main ridge was in their hands over a front of five miles and more. It was now possible to plan a general advance against the villages on the northern slopes of the watershed. Such an attack, if successful, would bring the British up against the rearmost of the enemy's original systems of defence, and would make the position of the Germans on their old front line S. of the Acre and immediately N. of it a pronounced salient.

Third Phase.—The next attack, therefore, opened a new phase in the offensive. Special preparations were made for it, and a week's pause after the taking of Ginchy allowed of many reliefs. Thus the ten divisions of the IV. Army employed in the attack of Sept. 15 included several which had not yet taken part in the operations, among them the Guards, the 6th, one of the original units of the 1914 "B.E.F." and the New Zealand. Similarly in the V. Army the Canadian Corps had replaced the Australians, who had since their capture of Pozières made considerable gains N. of the Albert-Bapaume road. In addition to these fresh troops it had been decided to employ in this attack a new weapon from which much was expected. Despite the great increase in the available artillery and ammunition and the great improvements in the methods for directing, controlling and observing artillery fire, barbed wire and machine-guns were still the chief assets of the defence and had held up attack after attack. The evolution of the "tank" had been a long process. The idea of an armoured motor-car capable of defying both machine-guns and barbed wire had occurred to many people from the earliest days of the deadlock set up by the extension of the trench line from Switzerland to the North Sea. To translate this idea into practical shape, to produce a machine capable of accomplishing what was wanted, had been the work of months of ingenuity, experiment, devotion and skill. Not the least remarkable feature had been the success with which secrecy had been maintained. The tanks at their first venture hardly fulfilled their designers' hopes and expectations—it would have been extraordinary if they had—but they did quite well enough to encourage the Allies and to shake the *moral* of the German infantry, to whom they came as an effective surprise.

The frontage included in the British attack stretched from just S. of Courcellette to just W. of Combles. That strongly fortified position itself was not to be attacked, as the capture of the high ground on either side of the valley would determine its fate, and S.E. of the valley the French, who had already on Sept. 12-13 attacked and taken Bouchavesnes with 2,000 prisoners, were ready to coöperate.

The attack proved a great if not a complete success. On the left the Canadians not only captured their objectives S. of Courcellette but exploited their success so well that the village itself, not part of the original objective, was carried and consolidated. To their right the 15th (Scottish) Div. captured Martinpuich, High Wood was at last completely cleared by the 47th Div. and farther to the right again the New Zealand and 41st Div., with some assistance from tanks, captured Flers and pushed some way beyond it. On the right the success was

less pronounced. A strong work between Ginchy and Morval known as the Quadrilateral held up the 6th Division. The tanks detailed to attack this point broke down and the gallant efforts of the infantry were unavailing. This check prevented the Guards Div. reaching their final objective, Lesbocufs, though they stormed their first and second objectives on the ridge S.W. of that village and maintained their position against counter-attacks. But with Lesbocufs and Morval, the objective of the 6th Div., still in German hands, the centre of the attack could not push forward without creating the same sort of situation as had prevailed on the right after the attack of July 14, and any further exploitation of the success was out of the question. Still, a big success had been achieved, a strong position had been broken into on a six-mile front, 4,000 prisoners had been taken, and the troops had the encouragement of having crossed the ridge and being able to see what lay on the farther side of the crest it had cost so much to gain.

The days that followed had to be occupied in reducing the Quadrilateral and in straightening out the line between Martinpuich and Flers. The 6th Div., not to be denied, pressed hard upon the Quadrilateral and after another unsuccessful attempt captured it on Sept. 18. But it is significant of the intensity and costliness of this fighting that the Quadrilateral had cost the 6th Division over 3,500 casualties. Its capture, however, allowed the line to be pushed forward within 1,000 yards of Morval and Lesbocufs, against which a new attack was in preparation.

Bad weather, however, delayed the delivery of this attack until Sept. 25. On this day the frontage attacked started at the Albert-Bapaume road but reached as far as the Somme. The French had, since capturing Bouchavesnes, improved their position S. of the Somme considerably by completing the reduction of Vermandovillers, Berny and Deniécourt, and they had on Sept. 20 successfully repulsed a strongly pressed counter-attack, N. of the Somme. Their objectives on this occasion included Rancourt and Frégicourt, Combles being dealt with indirectly by the capture of the heights on either side of it.

The "battle of Morval"—the official title for the attack of Sept. 25—was one of the most successful of the separate incidents of the Somme offensive. Except in the British centre at Guedecourt all the objectives were reached and carried before night-fall. On the left the 50th, 1st, New Zealand and 55th Divs. carried the line forward down the slopes N. of Flers and Martinpuich clearing two lines of trenches; on the right the Guards and 6th Divs. carried Lesbocufs and the 5th Div. took Morval, while Guedecourt also was captured next day (Sept. 26) by the 21st Div. assisted by a tank. The French were equally successful, and early on Sept. 26 British and French met in Combles, which was found full of stores and of German dead and wounded, the garrison having withdrawn just in time. Over 1,500 prisoners were captured by the British and nearly as many by the French, while signs were not wanting that the Germans were no longer putting up the stout resistance they had offered in the long struggles round Delville Wood and Guillemont. At several points large numbers of Germans surrendered or evacuated their positions almost without fighting. The strain of the continual bombardments and of the steady advance of the Allies was beginning to make itself felt.

The substantial success of Sept. 25 on the Allied right and centre was promptly followed up by victory in another quarter. Since July 1 there had been only one serious effort to renew the direct attack on the British left and the attempt of Sept. 3 had been a failure. Thiépval and all N. of it remained untaken. What progress had been made in this quarter had been from the S. and E. and it had not been rapid. The first real gain had not been made till the last half of Aug. when the scanty foothold already secured in the Leipzig salient directly S. of Thiépval had been enlarged by the 48th Div. This had been followed up by the capture (Aug. 24) by the 25th Div. of a trench known as the "Hindenburg trench." A violent counter-attack by a Prussian Guard Div. was successfully beaten off and minor gains had followed. Finally, on Sept. 14, a formidable redoubt known as the "Wonderwork," and situated just S. of Thiépval, was

stormed by the 11th Division. Meanwhile the progress of the Australians beyond and W. of Pozières had greatly increased the prospects of success in attacking Thiépval.

From Thiépval a trench ran E. towards Courcellette known as the Zollern trench, halfway along which and N. of Mouquet Farm was the Zollern redoubt. North of Thiépval was the strongly fortified Schwaben redoubt from which the Stuff trench ran E. to the Stuff redoubt S. of Grandcourt, being continued beyond the Stuff redoubt as Regina trench. The capture of this second line would allow the British to overlook the Ancre valley and would make the position of the Germans N. of the Ancre most precarious. It was natural, therefore, that the Germans should cling with great pertinacity to the Thiépval position, but despite a stubborn resistance the V. Army's attack (Sept. 26) achieved a conspicuous success. The Canadian Corps on the right carried their objectives and brought their line within striking distance of Regina trench. The 11th Div. stormed the Zollern redoubt, the 18th on the left had the satisfaction of capturing Thiépval itself with over 1,000 prisoners from a Württemberg regiment, which had held that stronghold for nearly two years and believed it impregnable. These successes were promptly exploited and the capture of the Stuff redoubt by the 11th Div. and of part of the Schwaben redoubt by the 18th (Sept. 27-28) left the Germans with only a scanty foothold on the main ridge.

Simultaneously with the success at Thiépval, lesser but useful gains had been made by the IV. Army, including the capture of Destremont Farm, S. of Le Sars (Sept. 20). This was followed up by the taking after a stubborn fight of Eaucourt l'Abbaye (Oct. 3), though a gallant effort by the Canadians against Regina trench (Oct. 1) proved unsuccessful.

Fourth Phase.—It was at this moment, when the enemy's fourth system of defences had been reached and the Allies seemed about to accomplish a break-through (for the new lines on which he was at work still farther to the rear were not to be compared in strength or completeness with those already overcome), that a long spell of bad weather set in. Nothing could have been more unlucky for the Allies. As has been said, the German infantry were no longer fighting with their old resolution, their counter-attacks were not pressed with the old devotion and determination. But the constant rain and the cloudy days, which formed almost the only intervals in the rain, prevented adequate observation of artillery fire and turned the already damaged battle area into an impassable quagmire. The troops already engaged in the Somme offensive had had ample experience of hardships and difficulties; those encountered in Oct. and Nov. altogether surpassed what had gone before. The state of the ground was appalling: it had become a sea of mud, through which even lightly equipped runners found movement almost impossible, much more men laden with rifle, equipment and ammunition. In these conditions an ordinary trench relief was an achievement, to attack across such ground a hopeless undertaking. It is easy now to argue that the attempt to continue the attack in such adverse circumstances was a mistake, and could achieve nothing commensurate with the casualties and sufferings which it entailed. But it must not be forgotten that to suspend the offensive meant relaxing the pressure on the Germans, on whom the strain of fighting under these conditions was scarcely less severe and meant also giving them time to convert their incomplete new lines into defences scarcely less formidable than those the Allies had so painfully slowly pierced. At the beginning of Oct. the Germans had been pressed back to their last really strong positions, and behind the line that ran from Sailly-Saillisel past Le Transloy and in front of Bapaume they had not had time to develop anything elaborate or formidable. The anxiety of the higher command to pierce the Le Transloy line without delay was natural enough.

The situation after the capture of Thiépval was that on the British left the Germans retained a precarious footing on the heights above St. Pierre Divion and Grandcourt, but that any substantial advance by the British centre, now almost down into the Ancre valley N. of Martinpuich and Guedecourt, would

turn the German positions lower down the Ancre. As before, however, the centre could not push on far with safety unless the right came forward level with it, and it was in front of the right that the German positions were most formidable. Their Sailly-Saillisel-Le Transloy line, itself strong, was covered by a long spur running in a N.W. direction and separating Lesboeufs and Guedecourt from Le Transloy and Beaulencourt. To capture this spur was indispensable before the Le Transloy line could be attacked. But a successful attack on the Le Transloy line was needed to open to the Allies the opportunity for an advance on a wide front in a N. and N.E. direction. Such a stroke would not merely outflank the Beaumont-Hamel position but the whole German position from Arras to the Ancre would be taken in rear. A dry Oct. might well have seen this hope realized and in Oct. 1916 there was no "Hindenburg Line" to bring an Allied advance to a standstill.

But with the weather as it was Oct. was a month of disappointment and scanty progress. The fighting was constant and costly. Trenches were difficult to take but much more difficult to consolidate or defend. The operations may be divided into three groups; on the right the French attacked and took Sailly-Saillisel but could make little progress N. and E. of it. In this quarter the repeated British efforts against the spur in front of Le Transloy resulted in the establishment of their line on its crest of the spur. In the centre, after the capture of Eaucourt l'Abbaye (Oct. 3) the chief gain was that the 23rd Div. secured Le Sars on Oct. 7. But to the N.E. of Le Sars the Allied progress was arrested by the gentle rise on which stands the mound known as the Butte de Warlencourt. This position was not particularly formidable in itself and in dry weather would not have held up the advance for long, but between the difficulty of accurately observing the fire of the supporting artillery and that of moving up the muddy slope on which the Butte stood attack after attack failed. The 47th Div. on Oct. 7, the 9th and 13th on Oct. 12, the 50th on Oct. 25 all found the Butte impregnable, though between Oct. 18 and 20 the 9th Div. did secure an advanced position in Snag trench, halfway up the slope, after a savage struggle.

The failure to take the Butte de Warlencourt or to make any substantial progress farther to the E. was to some degree compensated for on the left. Despite more than one repulse the line of Regina trench from the Courcellette-Pys road W. was stormed on Oct. 21 by the 15th, 18th, 30th and 4th Canadian Divs., and on Nov. 10 the Canadians extended their success by capturing the E. part of the trench on a front of half a mile.

By this time a sufficient improvement had taken place in the weather to allow of an operation on a larger scale than anything attempted since the battles of Morval and Thiépval. The more ambitious schemes for an advance across the Upper Ancre could not be put into force, but the German hold on the Beaumont-Hamel position had been weakened by the capture of Thiépval and it was decided to renew the attack in this quarter, the only portion of the frontage originally attacked which was still in German hands.

After a bombardment covering two days, the attack was delivered about an hour before daybreak on Nov. 13. South of the Ancre the 10th Div. cleared the German trenches N. of the Schwaben and Stuff redoubts and the 30th Div. took its farthest objective at St. Pierre Divion with remarkable ease and rapidity. North of the river the 63rd (Royal Naval) Div. fought its way forward to Beaucourt sur Ancre and held on tenaciously though in advance of the troops on its left. These, the 51st (Highland) Div., had been stoutly opposed at Beaumont-Hamel but had finally mastered the village, N. of which the 2nd Div. had carried the right portion of its objective. On the left, however, where the ground was specially heavy, the 3rd and 31st Divs. had been less successful; Serre had once again proved impregnable. But on the following day the success was exploited, Beaucourt was captured and the 51st and 2nd Divs. pushing forward along the spur N. and E. of Beaumont-Hamel established themselves on a line which secured Beaucourt on the N. and W. With this important gain of ground over 7,000

prisoners were taken, and to the Germans the quite unexpected loss of the long impregnable Beaumont-Hamel " was a particularly heavy blow " (Ludendorff). Advantage was taken of this victory to deliver a successful attack on a front of three miles against the German trenches on the slopes above Pys and Grandcourt (Nov. 18), but then the return of bad weather finally stopped the prosecution of active operations.

General Aspects.—The Allied offensive on the Somme had not yielded all the results that had been hoped for or that had at times seemed within reach. It was only natural that in some quarters the heavy cost at which the watershed between the Somme and Ancre had been mastered should be looked upon as altogether disproportionate to the gains, and that those who had not studied war sufficiently to realize that decisive victory is not to be had without a heavy price, and that it is not in achieving but in exploiting victory that the more tangible and spectacular gains are reaped, should be so disappointed as to overlook the substantial results which had been achieved. The Allies had begun the offensive with three main objects: to relieve the pressure on Verdun, to pin the enemy's main forces down to the western front, and, lastly, to wear down his powers of resistance. All these had been achieved, and of the three, the last, if the least tangible, was far from the least important. The 40,000 prisoners taken by the British and the 30,000 taken by the French might seem trilling in comparison with the vast captures made by both sides on the eastern front, but in quality the Germans taken on the Somme were very different from the half-armed Russians and the unenthusiastic mixture of nationalities who formed the Austro-Hungarian armies; and the decline of the German *moral*, admitted as it is by Ludendorff, outweighed in importance their losses in prisoners or material, considerable as these latter were. An eye-witness of the battle of Malplaquet wrote of that action, " the enemy was so advantageously posted that when the battle was over we wondered how we had surmounted the difficulties." Those who had been through the Somme might well have echoed his words, and despite the punishment they had received and the hardships they had endured the British and French had ample reason to be encouraged by their achievements. If the flower of the " new armies " of Great Britain and her Dominions overseas had been expended on the Somme, the Allies ended the year 1916 with a moral ascendancy over their enemies and with well justified hopes. It is only necessary to compare the strategical situation of Dec. 1916 with that of July 1 to see what a change had come over the war. On July 1 the Germans were certainly not contemplating attempting to negotiate a peace through the good offices of a neutral. And where had the change been brought about? Not on the eastern front, where Rumania had collapsed and the Russian offensive come to a standstill; not in Macedonia, where the capture of Monastir had been powerless to assist Rumania; not in the more distant theatres of war, where Kut was still in Turkish hands and the British had not yet reached the eastern frontier of Egypt; not in Italy, where the Austro-Hungarians were still holding up the Italian offensive across the Isonzo. Bad weather had prevented the immediate exploitation of the success earned in the struggles of July, Aug. and Sept.; changes of command and of plan were to throw away much of what the Allies had in their grasp early in 1917, but the change in the situation was the work of the Allied forces on the Somme.

(C. T. A.)

II. GERMAN OFFENSIVE OF MARCH-APRIL 1918

As soon as the general military situation towards the end of 1917 seemed to offer the Germans a possibility of conducting the war in the western theatre by means of attack, preparations for this were set on foot by the Supreme Command. The first German move was to fetch up all the troops from elsewhere that could be spared and establish, at least temporarily, until the strong American reinforcements were added to the Allies—a balance of forces in the western theatre of war, or, if possible, a preponderance on the German side. This would obtain the necessary time for rest and training. To this end German division

after division, and battery after battery, had been rolling up since the end of 1917 from Italy and the East into France. A number of heavy Austro-Hungarian batteries were also brought up. Finally 62 divisions and 1,706 batteries were made available for the main attack. For a second simultaneous attack in a different place these forces were not enough.

Systematic training for the attack was begun simultaneously behind the whole German front. Side by side with following out the instructions issued by the Supreme Command, the whole body of men had to be brought to exchange the defensive idea with which they had been living for the idea of the attack. The troops had to be taught the full use of machine-gun fire, guns and *minenwerfer*, and the support which airmen could give to infantry. They had to be trained to the utmost mobility and uplifted morally. The idea of surprise, which offered the only chance of the successful execution of a break-through operation, had also to be worked out in tactics.

Hand in hand with the equipping of the division chosen for the attack with horses and utensils of every kind went the collecting of munitions, supplies, building and sanitary materials, as well as the erection of railways, roads and battery positions.

Only a limited number of divisions could be equipped for the attack owing to the shortage of draft and horses. The building preparations were extended along the whole of the W. front so as to veil tactical purposes as long as possible.

At the end of Dec. 1917 the German Supreme Command had arranged for the mounting of quite a number of attacks. Although it was admitted that, for want of forces, the whole Allied front could not be attacked at once in order to find the suitable point for a break-through according to the Schlieffen idea, it was intended to keep the enemy as long as possible in ignorance of the German Supreme Command's actual intentions.

The decision as to which attack should actually be carried out was arrived at from a tactical point of view, strategical considerations being put aside. " Tactics had to be considered before purely strategical objects," writes Ludendorff, " which it is futile to pursue unless tactical success is possible. A strategical plan which ignores the tactical factor is fore-doomed to failure." Starting from this point of view Ludendorff decided to carry out the so-called " Michael " attack against the projecting southern sector of the British front. The attack was aimed at the British only, because they were still exhausted from the fighting of 1917 and it was desirable on general grounds to beat them first. It was to be executed at an early date independently of weather conditions. The sector to be attacked was thinly held and insufficiently fortified. It therefore seemed probable that the attack would succeed and that strategical use could be made of the break-through. It was unavoidable that the attack should take its course over the ground destroyed in the " Siegfried " retreat and the battle of the Somme.

The plans for the great attack were issued by the Supreme Command on Jan. 24 1918. The following individual attacks were to be prepared:—" Mars " (left wing) and " Michael I.," towards the N.E. past Bapaume, by the XVII. Army; " Michael II.," to the N. of the Omignon brook, by the II. Army; " Michael III.," on both sides of St. Quentin, by the XVIII. Army; " Archangel," south of the Oise, by the VII. Army. The " Michael " attack was proposed for March 20. The " Mars " and " Archangel " attacks were to follow a few days later, after the regrouping of the " Michael " artillery. The main attack was to break through the enemy front, and then, in conjunction with " Mars " left wing, to push on through Péronne-Arras. The XVIII. Army was to reach the line La Fère-Péronne. The " Archangel " attack was conceived merely as a diversion. The preparation of the attacks on Ypres-La Bassée (George I. and II.) was to be continued, the Hector-Achilles operations in the Argonne and Champagne were to be kept simmering. In case the Michael attack stopped short there was to be an attack by the III. Army. Instructions for demonstration actions were kept in reserve.

Rupprecht's group of armies, which, according to this plan, were to carry out the main assault with the XVII. and II.

Armies, were instructed to aim first and foremost at cutting off the British in the Cambrai bend. The armies were to advance with strong inner wings, the XVII. on Ypres and the II. on Equancourt. Subsequently the XVII. army was to deliver an assault in the direction of Arras-Albert and gradually roll up the adjacent British front, the II. Army to push forward in a westerly direction with the left wing on the Somme.

In the German Crown Prince's group of armies the XVIII. Army had to conquer the Somme and the Crozat Canal and eventually to extend to Péronne. If the II. Army should encounter any considerable resistance the XVIII. Army was to advance strong forces through Beauvois-Tertry to cut off the opponent in front of the II. Army. The Mars attack S. of the Scarpe was to follow the Michael attack as soon as possible and amplify the Michael operation. Farther N. preparations were also made to profit by it (Mars, N. Wulkürenritt).

The forces provided for the break-through were 15 attack divisions and 2 position divisions for the XVII. Army, 15 attack divisions and 3 of position for the II. Army, and 10 attack divisions and 5 of position for the XVIII. Army. Besides these, 3 divisions were retained by the Supreme Command for disposal, first at Bouchain, then at Denain. As regards artillery, 950 field batteries, 701 heavy and 55 heaviest batteries were called up. Added to these were a few Austro-Hungarian heavy batteries, inadequately supplied with munitions.

In the prolonged preparations now carefully made, the attack front was kept as lifeless as possible, with the troops unchanged and the day-traffic kept down. Detrainments went on a long way to the rear on a wide front, and all movements of importance were held over until night time.

In March, each of the four groups of armies executed a first attack. In the Crown Prince Rupprecht's group the preparations were so elaborate in the region of Ypres and Armentières that even the troops themselves and their leaders were convinced that a great attack was really imminent. The German Crown Prince's group made a show of preparing an attack in the neighbourhood of Reims. From the 14th onwards reconnaissance attacks, bombardment of the enemy headquarters, bombing by airmen and the bringing up of reinforcements, set in. The increased artillery activity continued until March 24. Gallwitz's group of armies carried out a great attack on Verdun systematically up to the stage when the infantry should have come in, with several days of artillery preparation, a gas attack, and the bombardment of railway stations behind the lines. Duke Albrecht's group feigned an attack on the Lorraine front, and carried out a heavy artillery battle from March 20 to 24.

The result of these German operations was to intensify the opponents' suspense to the utmost. The British put themselves in a position of defence against a great attack between Armentières and La Bassée and between Arras and St. Quentin, and shifted forces from Flanders to the south. The French evidently expected an attack at Reims. New defensive works arose everywhere in the chief opponents' lines. They reinforced their batteries and sought by increased activity on the part of the airmen and patrols, to penetrate the obscurity which enveloped the German mode of procedure.

In the front of the actual attack the Germans counted upon having, in front of the XVII. Army, 15 strong British divisions of the III. Army (General Byng), and in front of both armies 23 divisions of the V. Army (General Gough). The Germans assumed, further, that the leader of the combined operations of the Entente, General Foch, would have in readiness strong reserves, mainly French, somewhere in the region of Meaux behind the centre of the enemy front. The majority of the British reserves were supposed to be behind the centre of the British front. No signs of withdrawing were seen on the enemy's part. A restricted foreground was counted upon.

The actual forming up for deployment of the attacking armies began on March 10 with the munitioning. The artillery deployment followed, and the attack divisions next moved into their positions at the front. Everything passed off smoothly and without any great counter-measures being taken by the defence.

All the difficulties due to compressing within a narrow space great masses of human beings and piles of utensils and contrivances were easily overcome. The divisions were organized in groups, usually three lines deep, the first line being made the strongest in order to ensure rapid results at the beginning. The first line advanced close up to the front trenches on March 20, the second standing at a distance of 3-5 km. and the third 7-10 km. behind. The hindermost lines were looked upon as reserves for the higher command. They were not simply to follow up the others but to be fetched up according to the needs of the tactical situation.

The Supreme Command held in readiness, besides the above mentioned three divisions at Denain, other reserves behind the remaining army fronts, and reserved to itself the right of withdrawing forces from the front line when necessary.

On March 20 the attack divisions, protected by aircraft, were drawn up behind the position from which the assault was to be made. The deployment of the artillery and *minenwerfer* was complete and the munitions in readiness. Only the order to advance had still to come. But here the weather threatened to upset all plans, for the direction of the wind was such as would spoil the effect of the artillery's gas, and the fog would make the attack movement difficult for the infantry. By 12 at midday the weather conditions had so far improved, however, that it was decided to carry out the attack on March 21. On that day, accordingly, at 3:30 A.M., the gassing of the Allied batteries began. This was followed by a 3-hours' preliminary bombardment of the British positions by the German artillery and *minenwerfer*. At 9:40 A.M. the German infantry dashed forward to the attack. The mass of artillery then made a barrage, which, creeping gradually forward, was to pave a way for the infantry into the depths of the opposing trench system.

The attack itself turned out very differently at different points. In the XVII. Army, commanded by Otto von Below, the coöperation of infantry and artillery was not without its hitches. The barrage "ran away from the storming infantry," who only reached the opponent's first position and found itself in the evening before the strongly occupied second position. At Vaulx Vrancourt and to the N. of it, as also at Doignies, the British put up strong counter-attacks, to repel which several 2nd line German divisions had to be put in. The British defended themselves here with great stubbornness against the obvious danger of being shut off on the Cambrai bend.

The II. Army, commanded by von der Marwitz, pushed through to the line Gonzeaucourt-E. of Epéhy-Templeux le Guérard-Le Verguier. Their main battle raged around the high-perched village of Epéhy, which the XXIII. Reserve Corps failed to take in spite of heroic efforts. With this army only a small portion of the second line divisions needed to be brought up. There were no serious counter-attacks.

The greatest success was achieved by the XVIII. Army, commanded by von Hutier. Its right wing pushed through the second British position and took the Holnon Wood. The centre got through beyond Savy, Dallon, Fontaine les Clercs, and the left wing took Urvillers, Essigny le Grand and Beney, and forced the Oise crossing. The XVIII. Army also took the most booty.

On the whole a great initial success had been achieved. Everything depended upon whether it could be successfully developed.

The German Supreme Command was determined to order the continuation of the attack according to the results of the first day's fighting. It allotted the first reinforcements brought up to the XVIII. Army and the left wing of the II. Army, directing the XVIII. to ease the advance of the II. by pushing forward on Tertry. The II. Army was likewise to put its weight upon the left wing. On the second day the fighting was heavy, the chief burden falling on the infantry. A systematic preliminary bombardment was impracticable on account of the progress made on the first day, and it was a difficult matter to pull the batteries through the obstacles and shelled areas. The heaviest and most thankless task was once more allotted to the XVII. Army. Its infantry penetrated the second British positions time after time, only to be forced back just as often by strong count-

SOMME, BATTLES OF THE

er-attacks assisted by tanks. Not until the afternoon did they succeed, with considerable losses, in taking Croiselles, Vaulx Vrancourt and Morchies, and entering Hermies. To do this they had to be assisted by large portions of the third line. In the evening the army found itself once more up against another strongly held British position on the line Béhagnies, Beugnâtre-Beugny.

The II. Army had also had more hard battles to win. It took Epéhy and pushed forward as far as Fins-Longavesnes-Marquaix-Coulaincourt, capturing considerable booty. It was not able to interfere with the British evacuation of the Cambrai bend, owing to the slow progress made by the XVII. Army.

The XVIII. Army made a good advance encountering only slight resistance. It stormed Feuquières and forced a crossing over the Crozat Canal between Jussy and Tergnier. For March 23 General Ludendorff ordered an attack by the XVII. Army in the direction of Bapaume, to supplement the success of the II. Army, and an advance on both sides of the Somme by the II. and XVIII. Armies.

This day at last brought the reward of their heavy labour. The XVII. Army met with sharp opposition even now from newly put in divisions, but was able to take Monchy, Driencourt, St. Leger, Beaumetz, Lebuquière and Havrincourt.

The II. Army encountered heavy resistance on the right wing only, and was able to reach the line Neuville-Etricourt-E. of Bouchavesnes-E. of Péronne—the Somme at Brie, with only slight opposition. The XVIII. Army took the Somme crossing at Béthencourt by fighting, stormed Ham and crossed the Crozat Canal. Its left wing corps (the IV. Reserve) repelled the counter-attacks of 3 French divisions that were being hurried up as reinforcements in a bloody battle.

For the next two days the scene remained unchanged. The XVII. and II. Armies advanced towards the Ancre, fighting violently, the II. being more and more hindered by the shelled area of the Somme battle. But gradually a new front arose on the Ancre in front of these armies, stretching southward to the Somme. In the region of Albert the British executed one counter-attack after another, though with heavy losses.

The centre and right wing of the II. Army had, by March 26, reached Thiépval, Beaumont-Hamel, Mametz, Cornoy, Albert and Braye sur Somme. Certain portions veering in from the N. opened a way of advance for the lagging left wing, which was thus able to come up with the rest of the army on March 27 on arriving at Ville sur Ancre-Sailly. Meanwhile the resistance was visibly growing, and it was possible to calculate the point at which it would be equal to the decreasing pressure of the attacking forces.

The XVII. Army had been steadily fighting its way forwards through village after village. In proportion as the opponent's fighting power waned new forces were put in. He seemed determined that there should be no question of rolling up or breaking through his front at Arras under any circumstances. In spite of this the army managed to take Bapaume on March 24. Béhagnies, Sapignies, Gréville and Irles on the 25th, and to reach Boiry, Becquerelle, Hamelin-court, Achiet le Grand and Achiet le Petit on the 26th. The attacking power of the army was now exhausted. On the 27th it did no more than capture the village of Ablainzeville and repel the counter-attacks of new British forces with powerful artillery.

The II. Army progressed in much the same way. The XVIII. Army maintained its almost unbroken advance throughout the days from March 23 to 27. By the evening of the 25th it had reached Nyencourt, Curchy, Nesle, Hattencourt-Beaulieu-Bussy, and on the 27th was in possession of Pierrepont, Montdidier, Boulogne la Grosse and Lassigny.

At this point the great battle came temporarily to a close. General Ludendorff had, on the evening of March 26, shaped his plans with the view of dividing the British and French by a gradual left-wheel advance of the II. and XVIII. Armies against the French. To this end the Somme at Amiens, and the Avre had to be reached, and the operation continued towards the S.W. The original plans had thus undergone a complete change

in the course of its execution. It would now very soon be shown whether the tactical break-through could still be brought off in spite of the waning of the Germans' strength and the increase of the Allied resistance.

The course of events on March 27 did not come up to Ludendorff's arrogant expectations. It was impossible for the attacking force to know that in the direction of Amiens—the decisive point—the Allies had only very weak forces at their disposal on that day. In this case, as in every break-through, the difficulty of accurately estimating the exact effect presented itself. The difficulties of provisioning, too, made themselves increasingly felt in the shelled area of the Somme battlefield. The supply of munitions ceased, and the establishment of rearward communications had not kept pace with the advance of the attack. From certain signs it was evident that the German troops were not everywhere at their highest level of achievement and endurance. The losses, particularly those of the XVII. Army, exceeded what under the circumstances was the legitimate number.

Ludendorff therefore changed his intention once more on March 27. The XVII. Army was ordered to close down the attack. The XVIII. and the left wing of the II. were to renew their attack on the now isolated French on March 30 between the Somme and the Oise. This attack resulted in the filling out of the German line where it curved in S. of the Somme, and the taking of the localities Auber-court, Démuin, Moreuil, Sauvillers, Hargicourt, Contigny, Anainvillers, and Rollot—the so-called bridgehead of the Avre. But while the break-through at Amiens failed, the Germans were able to repulse the violent, though disconnected, French counter-attacks in every case. By April 4 the right wing of the XVIII. Army had still been able to take the heights W. of Moreuil. The II. Army reached the western border of Hamel and pushed forward almost to Villers Bretonneux and Hangard. The battle then ceased.

Later repetitions of the attack in the direction of Amiens had no better results. An assault on April 24 by the II. Army in the neighbourhood of Villers Bretonneux, in which tanks were used, made good progress at first but could not hold the ground gained. The battle ended therefore without any clear decision. Certainly the Germans had achieved an initial success such as had been denied to the Entente during the preceding 3½ years of hard struggle in spite of the masses of men and material put in; they had more than made good the ground lost in 1916, and had captured—apart from enormous booty—90,000 prisoners and 1,200 guns. The British army was heavily shaken; 20 French divisions had been drawn into the battle; but the war had not been won, and neither the transition to a war of movement, nor the separation of the French and British had been achieved. In the course of the battle 90 German divisions—almost half of the western army—had suffered more or less heavy losses. New and great efforts would be required for the fulfilment of Ludendorff's great aim.

Battles of Arras and the Oise.—An attempt was next made to extend the front of the attack on both sides. To this end Rupprecht's group of armies had been preparing since March 22 to carry out the Mars N. attack at an early date, and had allotted to the XVII. Army three divisions standing behind the VI. Army in view of this. To replace them four divisions of the IV. Army were sent to the VI. The group of armies hoped at last to break the British lines by delivering two attacks on their front—this one and the Walkürenritt by the VI. Army—while the II. and XVIII. Armies profited by their early success on the British right wing. But this plan had for the moment to be pushed aside as the Supreme Command placed all the pressure on the left wing of the Michael operation. Not until March 25 did Ludendorff revert to the extension of the attack on the British. He settled that the Mars attack should take place between the Loretto height and the Scarpe on March 28, together with a secondary attack south of that stream. The Walkürenritt attack on the Loretto height was to follow closely.

For this attack 7 German divisions were placed N. of the Scarpe, under the general command of the I. Bavarian Reserve Corps, and 4 S. of it under the general command of the III.

Bavarian and IX. Reserve Corps. But no success was obtained, although the divisions were mainly fresh ones. The work of attacking was hampered by the indistinct nature of the country and the endless maze of trenches. The British opposed the attack with fresh forces, and, particularly by the skillful use of their machine-guns, impeded the advance of the attacking force. North of the Scarpe the 1st line divisions, after some insignificant successes at the start, met with strong British counter-attacks, which threw back the attackers for the most part to their starting positions. Only the two localities, Gravelle and Rocux, remained in German hands. The Command did not put in any reserves.

South of the stream the localities of Neuville and Aytte yielded to the bold assaults of the German divisions fighting in that quarter, but no decisive success was attained. The taking of several thousand prisoners, and heavy losses on the Allied side, were the only positive results of the Mars attack, which had failed for two reasons—it was obviously on too narrow a front and had not been launched as a surprise.

The Supreme Command now gave up the VI. Army attack on the Loretto height, and ordered the XVII. Army, including its right wing, to stand on the defensive.

The extension of the attack S. of the Oise had no such wide operative aims. It was designed in the first place to protect the projecting left flank of the XVIII. Army and the road running behind it through La Fère-Chauny-Nayn, which was indispensable for bringing up drafts. To ensure this the Ailette line, which cut off the reëntering angle between the XVIII. and VII. Armies, had to be won. The task was entrusted to the general commands of the VIII. Army Corps and the VIII. Reserve Corps under the leading of the 7th Higher Army Command. The attack was led from the N.E. in view of the difficult Oise crossing. The attacking force, on April 6, took the French—who were apparently in no great strength—obviously by surprise, and pushed through South Chauny and Amigny to Marizelle and Barisis railway station. On April 7, after a short preliminary bombardment, the attack was continued, and Pierremande and the Coucy Wood were reached with only slight opposition. On the 8th the VIII. Army Corps advanced to the Ailette, S. of Le Bac d'Arblincourt, and stormed Champs. The VIII. Reserve Corps captured Coucy le Château, and reached the road Coucy-Landricourt-Arizey at nightfall. Finally on the 9th the two corps won the Oise-Aisne Canal along the whole front.

In a 4-days' struggle the problem had been smoothly solved. The victors held 2,300 prisoners. The front had been considerably shortened, and the possibility of successful attacks even against French defenders had been established. (W. M.-Lo.)

III. THE BATTLE OF AMIENS, AUG. 8-22 1918

At the beginning of the fourth week in July, the German offensive on the Marne and in Champagne, which had been intended by their Higher Command as decisive, had been brilliantly repulsed by an Allied counter-blow, which had not only thrown back the enemy over the Marne but was forcing him back to the Vesle. Gen. Foch was resolved to follow up the advantage thus gained and assume the offensive on all his front as soon as possible; but it was essential before so doing to clear the main railway lines running laterally behind his front, several of which were menaced or blocked by the enemy. The most important of these was the Paris-Amiens line, and it was therefore decided that the first measure should be the freeing of this railway by a joint Franco-British attack on a wide front E. of Amiens. This operation was discussed first at a council of the four Allied commanders-in-chief, held at Bombon, near Melun, on July 24 1918 and further in a conference between Gen. Foch and Sir D. Haig on the 26th, and was finally embodied in a directive issued by the Allied Generalissimo on the 28th. It was therein laid down that the offensive should be conducted by the IV. British and I. French Armies, under the command of Field-Marshal Haig; that covered by the Somme, it should be pushed as far as possible in the direction of Roye, and that the road from Amiens to that place should be the dividing line

between the two armies. The date fixed, at first Aug. 10, was later advanced to Aug. 8.

Preparation for the British Attack.—An operation similar to that ordered had for some time been contemplated by the IV. Army, and preparations for it were therefore pressed on from July 26 onwards. At this date the army, under Gen. Rawlinson's command consisted of the Australian (Monash) and III. Corps (Butler), (8 infantry divisions and one cavalry division), on the front Albert-Villers-Bretteux. By the date of the attack it had been reinforced by the Canadian Corps (Currie) (4 infantry divs., another Australian infantry div., and 2 cavalry divs.), while the artillery was brought up to a total of over 2,000 guns, the aircraft to 28 squadrons and the tanks to 456 machines, 96 being whippets. The difficulties of effecting the concentration of these masses of troops and material, while keeping it secret from the enemy, were successfully overcome by means of elaborate precautions surpassing even those taken by the Germans before their spring and summer offensives. The cavalry, whippet tanks and part of the artillery were moved into the IV. Army area by road, the remainder (far the larger proportion) of the troops and material, being brought up in the period Aug. 1-8 in some 300 special trains. It was regarded as of the utmost importance to keep secret the arrival of the Canadians; in order to deceive the enemy, the troops themselves were deceived; Canadian units were sent from Arras into the trenches in Flanders, and the corps was actually brought into line, only a few hours before the attack, relieving the right of the Australian Corps, which had by Aug. 1 taken over the front from the French as far as the Amiens-Roye road. The precautionary measures taken were entirely successful in their object of ensuring that no warning of the attack should reach the enemy.

The front of the IV. Army attack extended from the Ancre S. of Albert to the Amiens-Roye road, a frontage of some 13 m.; three successive objectives were assigned, at distances, respectively of about 2-2½, 3-5, and 6-8 m. from the original starting line, which would bring the army eventually on the line of the "Amiens outer defences," on the front Le Quesnel-Harbonnières-Morcourt. The country, open rolling downland, was favourable for the operations of all arms; the enemy's defences were not formidable. The hostile forces believed to be available to oppose the British, consisted of the LI., XI. and XIV. German Corps (seven divisions in first line and eight in support and reserve) belonging to Gen. v. der Marwitz's II. German Army.

By the morning of Aug. 8 all preparations for the battle had been successfully completed and the British forces were, all unsuspected by the enemy, about to enter on the first stage of their march to the Rhine.

The British Offensive on Aug. 8.—Punctually at 4:20 A.M. on the morning of Aug. 8 the British infantry and tanks, under cover of a powerful barrage, debouched to the assault. Thick ground-mist veiled their advance from the eyes of the Germans, who were completely surprised and in an instant overwhelmed with little resistance. The Canadian Corps sector extended from the Amiens-Roye road to the Amiens-Chaulnes railway; 156 tanks coöperated in the attack of this corps. Opposed to them was the 119th German Div., which was in process of being relieved by the 117th Division. The 3rd Canadian Div. on the right of the line, making light of the difficult task of debouching from a narrow bridgehead on the S. bank of the Luce river, set foot on the plateau between that stream and the Avre, captured Hangard and Dëmuin, and by noon had carried its front forward to the second objective, between Cayeux and Mezières. Thenceforward the 3rd Cavalry Div. took up the advance, followed by the 4th Canadian Div.; the cavalry, after taking Beaucourt, were held up by machine-gun fire, and though the infantry when they arrived succeeded in pushing forward, it was not found possible to reach Le Quesnel, the final objective, which at fall of night was still strongly held by the enemy. The centre and left Canadian Div., and the 1st and 2nd, attacked each on a front of one brigade, employing a separate brigade for each successive objective; the 1st Div. met with little serious

opposition as far as the first objective, which it reached at 6:20 A.M. but the 2nd Div. only attained it an hour and a half later, having had heavy fighting at Marcelet. At 8:20 A.M. the advance was resumed, and again the 1st Div. had the easier task, the German machine gunners putting up considerable resistance against the 2nd Division. Two brigades of the 1st Cavalry Div. now passed through to the front, and drove far into the hostile territory, capturing Caix, and attaining the final objective, in conjunction with the Canadian infantry, which moved behind them clearing up the ground already passed over by the cavalry. By 5:15 P.M. the Canadian Corps had, with the exception already noted on its extreme right, carried out its appointed task; it had penetrated the enemy's defences to a depth of over 8 m., capturing 12 villages, over 6,000 prisoners and 160 guns.

The Australian Corps advanced between the Amiens-Chaulnes railway and the Somme against the 41st, 13th and parts of the 108th and 43rd German Divs. The Australians had their 2nd and 3rd Divs. in first line and their 5th and 4th in support, the 1st Div. being in reserve N. of the Somme; 168 tanks were attached to the corps. The corps was drawn up by its commander in such a manner as to necessitate a double "leap frogging" of its divisions, while equalizing the exertions demanded of them and the distances to be traversed by them; and this complicated manœuvre was carried out with entire success. The 2nd and 3rd Divs., assisted effectively by the tanks, carried Warfusée and Cérisy, and then relinquished the attack to the 5th and 4th Divs. which pushed forward beyond Baronvillers and Morcourt, despite heavy flanking fire from the German artillery on the N. bank of the Somme. On the second objective being reached at 10:30 A.M. a brigade of the 1st Cavalry Div., with 16 whippet tanks, passed forward to Harbonnières, and an armoured car battalion raced forward down the Amiens-Brie road, scattering death and destruction far to the E. in the enemy's back areas. Behind them the Australians, throwing back their left to face the enemy on the N. bank of the Somme, pushed forward their centre and right to the final objective, just W. of the line Vauvillers-Proyart, where they found the cavalry held up. In the space of under six hours, between this opening of their attack at 6:20 A.M. and the attainment of the above line about midday, the Australian Corps had occupied seven villages, and taken over 8,000 prisoners, 173 guns and much other booty too numerous to mention.

On the N. of the Somme the operations of the III. Corps had not, however, met with the expected measure of success. It had been intended to advance with the 58th, 18th and 12th Divs. to a river from the line W. of Etinchem to W. of Morlancourt, thus securing the left flank of the main attack S. of the Somme; 34 tanks were detailed off to assist this attack. The programme of attack was disarranged by a partial advance of the enemy on Aug. 6 which forced back the 18th Div., and from the first moment difficulties were met with. Sailly Laurette was carried after stiff fighting by the 58th Div. and eventually the first objective was reached along the whole corps front. The further advance of the 58th Div. broke down against the resistance of the enemy holding the Chipilly spur and the 18th Div., which succeeded for a time in gaining ground farther to the N., were counter-attacked and forced to fall back. The enemy on the III. Corps front was not surprised, and fought well, and the attacking infantry were unable to find much support from the tanks, for which the ground was unsuitable in many places; 2,400 prisoners were taken by the III. Corps, together with 40 guns.

The results of what had undoubtedly been the most successful day's battle waged hitherto by the British army in the World War, and one of the finest British victories of all time, were the complete defeat of 11 German by 11 British divs., a gain of ground to an average depth of 6 to 7 m. on a front of 8, and the capture of close on 17,000 prisoners, 373 guns, several thousand machine-guns, and quantities of ammunition and stores. Most important of all, the battle revealed to the enemy Higher Command weaknesses hitherto unsuspected in their army, and destroyed the last hope of German victory. "It was," says

Ludendorff, "the black day of the German army in the war. It was the worst experience I had to go through. It marked the decline of our fighting strength and destroyed our hopes of a strategic improvement. To continue would be a gamble. The war would have to be ended."

Operations of I. French Army around Montdidier (Aug. 8-11). The plan of Gen. Fayolle, commanding the French reserve group of armies, involved not only the participation of Gen. Debeney's I. French Army in the British operations N. of Montdidier but a subsequent extension of the attack to the S. of that town by the right wing of that army and eventually as far as the Oise by the French III. Army (Gen. Humbert). Gen. Foch sanctioned this scheme on Aug. 3, and it was decided that the attack S. of Montdidier should take place on the 9th and that of Humbert's army on the 10th.

The French I. Army at this time held a line from the British right flank near Domart to Castel on the Avre and thence along the W. bank of that stream to Courcelles, S.E. of Montdidier, whence the French III. Army continued the line to the Oise. Debeney had under his command the XXXV., X., IX. and XXXI. Corps (in line in that order from right to left) and the II. Cavalry Corps in reserve, in all 12 infantry and 3 cavalry divisions. In face of him stood the 2 left divisions of the German LI. Corps, of von der Marwitz's II. Army, as far as Moreuil, and 7 divisions in line with 2 in reserve, belonging to Von Hutier's XVIII. Army, from Moreuil southwards. The enemy on this front had recently withdrawn his line behind the Avre as a result of several small French operations on the W. bank and was therefore well on the alert.

Debeney's plan for the forthcoming operations consisted first of an advance by his two left corps in the angle between the Luce and the Avre in conjunction with the British right, followed by the passage of the Avre and the Trois Doms and a rapid advance to the plateau around Hangest on both sides of Montdidier by his centre and right, and the capture of that place. The whole army was then to push forward astride the Avre in the direction of Roye.

This programme was carried out without a hitch. The French bombardment commenced at 4:20 A.M. on the 8th, the hour of the British attack, and the infantry and tanks of the XXXI. Corps debouched between the Luce and Moreuil at 5:15 A.M. The German LI. Corps on this part of the front, was, contrary to expectation, taken unawares and put up little resistance; many prisoners were captured while engaged in cutting corn in the fields. Moreuil was taken and the way cleared for the IX. Corps farther S., which about 9 A.M. began to cross the Avre on foot-bridges thrown under cover of darkness early that morning. Here there was stiff fighting, and it was not till late in the day that the tanks were got across the river and cleared the way for the infantry, which at nightfall had reached the line Fresnoy-Plessier. Behind the IX. Corps, the X. was passing the Avre, and preparing for its S.E. advance on the morrow to encircle Montdidier from the N., while the XXXV. Corps was about to execute a similar manœuvre from the south.

The second stage of the operations commenced early next morning, the 9th. In order to secure the left of the X. Corps in its advance on Montdidier the XXXI. Corps attacked Hangest and occupied it about 11 A.M. The X. Corps, passing the Avre and the Trois Doms in its turn, took over the IX. Corps, and, assisted by the latter's artillery as well as its own, pushed forward to the E., meeting with considerable resistance, while the XXXV. Corps, debouching against Assainvillers at 4 P.M., took the enemy by surprise and advancing some 3 m., reached and cut the Montdidier-Roye road near Faverolles. The garrison of Montdidier, their retreat threatened from two sides, fell back hastily under cover of darkness by the road to Guerbigny, leaving behind a rearguard which fell into the hands of the French X. Corps on their entry into the town on the morning of the 10th.

Debeney, urged by Foch in a personal letter "to push forward towards Roye and there join hands with the French III. Army" (which was due to open its attack between Courcelles

and the Oise on the 10th), decided, now his army was successfully reunited astride the Avre, to press his advantage in conjunction with the British on his left. The disaster to the German II. Army in the N. had rendered the position of the XVIII. Army, which was facing Debeney, so difficult that it had to throw back its right flank to W. of Roye—a movement which was carried out on the night of the 9th. By the evening of the 10th the I. Army following up the retiring enemy had reached the line Andechy-Bus, and on the next day a further slight advance was made on either wing of the enemy, Lechelle and Tilloloy being taken by the XXXI. and XXXV. Corps.

By now the German XVIII. Army, although its attention was distracted by the advance of the French III. Army against its centre and left, was reconstituting a solid line in the old French zone of 1916. Von Hutier, whose forces had been increased from 15 to 18 divisions by the 11th, established them in depth on two successive lines of trenches, with a strong belt of wire in front, all lines of approach being swept by direct and indirect machine-gun fire. A continuation of the rapid advance of the French I. Army was under these circumstances out of the question, and it was necessary to resort to slower and more thorough measures for overcoming the German resistance which was day by day hardening in proportion as further fresh reinforcements arrived.

Continuation of British Advance (Aug. 9-11).—It was decided by Gen. Rawlinson that the IV. Army should on the 9th continue its advance to the line Roye-Chaulnes-Bray-Dernancourt. The main attack was entrusted to the Canadian Corps which was to push S.E. to the line Roye-Hallu, while the Australian Corps was to secure its left between the latter place and Méricourt, and the III. Corps to advance to Etinehem and form a strong defensive flank on the N. bank of the Somme.

The Canadian attack, on the 9th, failed to attain all its objectives. Assisted by the 2nd Cavalry Div., it none the less effected a deep advance of some 4 to 6 m., secured eight more villages, and halted for the night on the line Arvillers-Rosières. To its left the Australians advanced their front between the Chaulnes railway and the Amiens-Brie road as far as Lihons hill, W. of Lihons village, and Framerville, after stubborn fighting. The III. Corps, reinforced by an American detachment, carried all its objectives for the day, clearing the Chipilly spur and taking Morlancourt. The German II. Army, still much disorganized, had been reinforced by six additional divisions from the XVIII. and IX. Armies, sent up by train and lorry and thrown straight into battle, often without their artillery, and its resistance had noticeably stiffened.

The British advance was continued on the 10th. The Canadians, now opposed by fresh troops from the XVIII. German Army, succeeded in attaining with its left the front assigned to it at Hallu and Fouquescourt but failed to get its right forward to Roye, the western suburbs of which were stoutly held. The Australian Corps which had now extended its left astride the Somme, in order to secure effective coördination of the operations on both its banks, had severe fighting on Lihons hill and was held up by determined German counter-attacks. Operations were undertaken on both banks N. of the Somme under cover of darkness, the plan being to encircle the hostile positions in the Etinehem and Méricourt bends by drawing a cordon across the bases of these bends. Etinehem and all its garrisons were easily taken, but the attack on Méricourt was broken up by hostile bombing planes and had to be completed on the 11th.

The IV. Army orders for this day's operations were that the Canadians and Australians should continue their advance to the line of the Somme and secure the crossings from Offoy (E. of Ham) to Bray. During the 10th and 11th, however, 8 more German divisions had come into line and delivered a series of vigorous counter-attacks which had the effect of putting a stop to any real British advance. The Canadian attacks were cancelled and the Corps had hard work to hold its ground. The Australians captured and held Lihons but could get no farther.

In fact, it was now clear that to push the offensive further would lead to disproportionate loss with little corresponding

gain. The German II. Army had reformed its front, shattered on the 8th, with fresh troops drawn from the XVIII. and IX. Armies and from Prince Rupprecht's group in Flanders, and settled itself on the edge of the area devastated in the Somme battles of 1916, where a maze of old trenches, wire, and shell holes rendered defence easy and rapid advance impracticable. The British IV. Army had engaged all its 13 divisions, and its units were tired and in need of a breathing space. Gen. Rawlinson therefore decided on the 11th to allow his troops a few days' rest, while preparing for a renewal of the attack on the 15th. The units in the line were relieved and the tired infantry together with the cavalry were withdrawn into reserve.

French I. Army's Operations (Aug. 12-22).—On Debeney's front also during this period, minor activity took place, resulting in merely local advantages to the French. On the left of the I. Army, the line was drawn closer to Roye on the N.W. and W., while on the right the XXXV. Corps took Reuvraignes on the 20th. In this area, however, the German XVIII. Army had put into line no less than 10 divisions, while on the whole front between Roye and Lassigny a total of over 20 divisions were engaged between Aug. 9 and 22 against the French I. Army. Thanks to the employment of these strong forces, and to the increasing facilities for defence afforded by the shattered and intersected country into which the battle line had now been carried, the German XVIII. Army was enabled to maintain its ground to the W. and S. of Roye until the pressure of events elsewhere compelled its withdrawal in conformity with the armies on either flank at the end of August.

The operations of the French I. Army since Aug. 9 had resulted in the reconquest of an area of ground to a depth of 10-15 m. and the capture of some 12,000 prisoners and over 100 guns, besides much other material and stores.

British Operations (Aug. 12-22).—The IV. Army offensive planned for the 15th did not take place and only partial actions were carried out on its front during the period from the 12th to the 22nd. British attacks alternated with German counter-attacks with no great change resulting in the situation. Thus on the 12th the Australians took Proyart, while on the 15th the Canadians secured Damery and Parvillers. On the 17th Sir D. Haig decided that the next large scale attack by the British should take place on the I. and III. Army fronts; the Canadian Corps left the IV. Army, the French taking over its sector as far as S. of Lihons and the remainder of the IV. Army line, which on Aug. 22 ran from Damery by Lihons and Proyart to Dernancourt, was left to the 12 divisions of the Australian and III Corps. Facing them the German II. Army had available 26 divisions, of which, however, only 16 were in good fighting trim.

During the period from Aug. 8 to Aug. 22 the IV. Army had forced back the Germans to a depth of 12 m., had defeated or engaged with its own 13 divisions no less than 27 of the enemy's, had taken from him 23,000 prisoners and 400 guns and had killed and wounded more than an equivalent number of his men at a cost to itself of some 27,000 total casualties.

Offensive of French III. Army (Aug. 10-22).—In accordance with the scheme of Gen. Fayolle, already mentioned, the attack of the French III. Army was launched on the early morning of the 10th. The XXXIV. and XV. Corps (7 divs.), on a front of 14 m., from Courcelles to the Oise, were opposed by 7 German divisions in line and one in reserve, forming the centre and left of the German XVIII. Army. The objective of the French offensive was assigned as the line Lassigny Noyon. The nature of the ground in front of Humbert's right, a tangled and broken mass of wooded hills, known as the "Petite Suisse," forbade any rapid advance in that quarter, and recourse was had therefore to an enveloping movement by the left (XXXIV.) Corps of the III. Army, which was directed to turn the highland by the north. At 4:20 a.m. on the 10th the attack commenced without artillery preparation; little resistance was met with at first, and before noon a penetration of some 3 to 4 m. had been effected, the infantry reaching the front Onvillers-Macqueglise. The advance was continued during the afternoon against the high ridge of Boulogne, while French aeroplanes carried out a bombing raid

on Lassigny, and by nightfall the XXXIV. Corps was on the line Onvillers-Boulogne-La Neuville.

On the 11th the XV. Corps on the right of the army was put into the attack directly against the front of the "Petite Suisse," while the XXXIV. continued to progress to the N. of it. The resistance of the XVIII. German Army, reinforced by an extra division, stiffened appreciably during the day, and all along the line there was hard fighting. Hostile machine gunners ensconced in the broken country made the advance slow and painful; every foot of ground had to be fought for and the French could only advance step by step. After a week's fighting, the "Petite Suisse" still remained partly in German hands, while the French left wing was not yet in possession of Lassigny. The German XVIII. Army which, as already mentioned, had brought back its right flank to Roye on the evening of the 9th and was now also withdrawing its left along the Oise, fought stubbornly to secure time for the evacuation of its artillery and material. Nevertheless the French III. Army made daily headway.

It was not, however, till the offensive by the French X. Army on the E. of the Oise threatened by its rapid progress to imperil the retreat of the Germans in the "Petite Suisse" that Humbert's troops could finally force them from their stronghold. On the morning of the 21st the German XVIII. Army fell back all along the line; the French infantry occupied Lassigny and cleared the wooded highland and by the 22nd had reached the line of the Divette, where they were halted to regroup and prepare for a renewed advance.

In the thirteen days' fighting Humbert's 7 divisions had driven from their strong vantage ground 8 enemy divisions and had taken from them 5,000 prisoners and 100 guns.

General Results of the Battle of Amiens.—The course and results of the fortnight's fighting between Aug. 8 and 22 may be summed up as follows:—The three Allied armies engaged (IV. British, I. and III. French), with 32 divisions, had attacked and defeated the II. and XVIII. German Armies, in all 42 divisions. Of these 42 divisions 30 were originally in line or reserve at the moment of the attacks, and 12 were put in from other parts of the front, being drawn from seven different German armies, belonging to three different army groups. The Allies advanced to a depth of between 6 and 14 m. on a front of 47, taking a total of 40,000 prisoners, 600 guns, thousands of machine-guns, quantities of ammunition, matériel and stores of all kinds. A wide breach had been made in the German front, susceptible, as events showed, of being rapidly widened to either flank by further Allied attacks. A shattering blow had been dealt to the *moral* of the German army and the German Higher Command, from the effects of which neither was destined to recover. The Battle of Amiens was the first page in the story of the Allied victory of 1918. (X.)

IV. BATTLE OF BAPAUME-PÉRONNE, AUG. 21-SEPT. 2

The first conception of the battle of Bapaume-Péronne was laid down in a directive from Marshal Foch to Field-Marshal Haig, written on Aug. 10—that is at the moment when the battle of Amiens had just been crowned with a brilliant success, and the enemy was retiring E. along the whole front from the Ancre to the Oise under the pressure of the British IV. and French I. and III. Armies. In this directive it was enjoined that "enterprises of the British III. Army in the general direction of Bapaume and Péronne should be prepared as soon as possible," while "the action of the British IV. Army should be pushed in the direction of Ham." Further instructions for the enlargement of the battle towards the N. to take place simultaneously with its extension to the S. by the advance of the X. French Army between the Oise and the Aisne (timed for Aug. 20), were sent to Haig on the 12 and it was finally decided that the advance of the III. Army should commence on the 21st and be followed by a general offensive on the front of that Army and the IV. Army two days later.

The general scheme of the operations between the Somme and the Scarpe was based, according to Lord Haig, on the following considerations:—

"The enemy did not seem prepared to meet an attack in this direction and owing to the success of the IV. Army, he occupied a salient, the left flank of which was already threatened from the south. A further reason for my decision was that the ground N. of the Ancre river was not greatly damaged by shell fire and was suitable for the use of tanks. A successful attack between Albert and Arras in a S.E. direction would turn the line of the Somme S. of Péronne and gave every promise of producing far-reaching results. It would be a step forward towards the strategic objective St. Quentin-Cambrai. This attack moreover would be rendered easier by the fact that we now held the commanding plateau S. of Arras about Bucquoy and Ablainzeville, which in the days of the old Somme fighting had lain well behind the enemy's lines. In consequence we were here either astride of or to the E. of the intricate systems of trench lines which in 1916, we had no choice but to attack frontally, and enjoyed advantages of observation which at that date had been denied us. It was arranged that on the morning of Aug. 21 a limited attack should be launched N. of the Ancre to gain the general line of the Arras-Albert railway, on which it was correctly assumed that the enemy's main line of resistance was sited. The day of Aug. 22 would then be used to get troops and guns into position on this front and to bring forward the left of the IV. Army between the Somme and the Ancre. The principal attack would then be delivered on Aug. 23 by the III. Army and the divisions of the IV. Army N. of the Somme, the remainder of the IV. Army assisting by pushing forward S. of the river to cover the flank of the main operation. Thereafter if success attended our efforts, the whole of both armies were to press forward with the greatest vigour and exploit to the full any advantage we might have gained."

The line of the British IV. Army at the date of the opening of the new battle on Aug. 21 ran from Fransart by Chilly, Proyard and Dernancourt to Albert. The right of this line as far as the Bray-Corbic road was held by the Australian Corps (Monash) with five divisions (from the right, 4th Canadian, 4th Australian, 32nd, 5th Australian and 3rd Australian) in line and three (1st Canadian, 1st Australian and 2nd Australian) in reserve. To the left of this the III. Corps (47th, 12th and 18th Divs. in line and 58th in reserve) continued the line to the army boundary northward of Albert on a front running along the W. bank of the Ancre as far as Beaucourt and thence W. of Puisieux, Bucquoy and Moyenneville to the Cojeul. The III. Army held the line in order from the S. with the V. Corps (Shute) with the 38th and 21st Divs. in line and the 17th in reserve, from N. of Albert to Beaucourt; the IV. Corps (Harper) with the 42nd, New Zealand and 37th Div. in line and the 5th and 63rd in support, extending as far as opposite Ablainzeville; and the VI. Corps (Haldane) (2nd Guards, 56th and 52nd Divs. in front line, with the 3rd in rear), as far as the army boundary.

Facing these troops the German II. Army (v. Marwitz) held the front opposite the IV. British Army, from N. of Roye to N. of Albert. This army, after its battering on Aug. 8 and succeeding days, held its front with 16 divisions, retaining 7, mostly exhausted and reduced in numbers, in reserve. The XVII. Army (Otto v. Below) was on the right of the II. extending as far as Avion, S. of Lens. On the eve of the attack this army had 11 divisions in first line and 2 in reserve. Both of these armies, together with the IX., to the left of the II., belonged to the newly-formed Army Group of von Boehm, whose area of command thus extended from N. of the Scarpe to the Aisne.

First Stage of III. Army's Advance (Aug. 21-26).—The main attack on the front of the British III. and IV. Armies was timed for Aug. 23 and the two previous days were to be in some sense only a prelude. The operation to be undertaken on Aug. 21 consisted of an advance by the IV. and VI. Corps on a front of 9 m. from opposite Miraumont to Moyenneville, while the left division of the V. Corps secured the right flank of the attack along the Ancre. The general objective was to be the line of the Arras-Albert railway, the attainment of which involved a penetration of the hostile front to a depth of 2 to 3 miles.

The attacking infantry, supported by tanks and covered by a strong barrage, moved forward at 4:55 A.M. The enemy was fully aware of the probability of an offensive on his XVII. Army sector and had adopted his well-tried system of defence in depth, the positions forward of the railway being lightly held by weak forces. These were rapidly driven in along the whole front of attack, their task being rendered difficult both by thick mist and smoke thrown out to cover the advance of the assaulting infantry.

While the 21st Div. of the V. Corps pushed forward along the right bank of the Ancre as far as Beaucourt and set to work to prepare a passage over the flooded and marshy stream at St. Pierre Divion, the 42nd, New Zealand, and 37th Divs. of the IV. Corps carried their first objective, the high ground E. of Bucquoy and Ablainzeville, and then gave place to the 5th and 63rd Divs., which carried the line up to the final objective W. of the railway. Further to the N. the 2nd and Guards Divs. of the VII. Corps, assisted by the 3rd Div., which was leap-frogged over the 2nd for the last stage of the advance, also carried out their allotted task, and though the fog, which had at first favoured the attacking troops caused some little confusion and loss of direction, succeeded not only in reaching but in crossing the railway E. of Courcelles and Moyenneville. Over 2,000 prisoners were captured along the front of attack, of which 1,400 fell to the lot of the IV. Corps.

The German XVII. Army, in view of the loss of its forward positions, requested permission to retake them by a counter-offensive, which was delivered in force on the 22nd, and drove in parts of the new line both in the IV. and VI. Corps sector. It failed however to gain any decided advantage, as the Germans themselves admit, and meanwhile the preparations for the general advance on the whole of the IV. and III. Army fronts on the 23rd were being rapidly completed. At the point of junction of the armies the 38th Div. of the V. Corps, in cooperation with the III. Corps, carried out a series of operations which had as their result the occupation of Albert, and the seizure of points of passage which rendered it possible to throw strong forces to the E. bank of the Ancre in preparation for the morrow.

The main phase of the III. Army's operations began in the morning of Aug. 23, the various formations attacking at different hours along the whole front of 16 m. from Albert to the Cojeul. The enemy resisted with determination, but considerable progress was made all along the line. On the right the V. Corps, still acting in close conjunction with the III. Corps to the S. of it, pushed out its right, the 38th Div., E. and N.E. from Albert and completed its occupation of the hills overlooking the town. By the end of the day this division held a line from just W. of La Boisselle to Aveluy, while its left brigade had thrown parties across the marshes E. of Hamel, where they held on all night in face of repeated German attacks. On the front of the 21st Div., on the left of the V. Corps, only small attacks took place, but the IV. Corps to the N. of the Ancre, commencing its advance at 11 A.M., with the 42nd, New Zealand, 5th and 37th Divs., carried the railway, the enemy's main position, from N. of Miraumont to Achiet le Grand, and pushing forward further on the left, reached a line from Bihucourt to Loupart Wood, whence the front at the end of the day ran sharply westwards N. of Ires and N. and W. of Miraumont. On the VI. Corps the attacking divisions, from right to left were the 2nd, 3rd, Guards, 56th and 52nd. The 3rd Div. opened the advance at 4 A.M. with a successful attack on Gomiécourt, after which at 11 A.M. the 2nd Div. passed through on either side of the village to continue the advance, its objective being the line of the Arras-Bapaume road between Sapignies and Ervillers. The right of the attack made little progress, but on the left Ervillers was taken early in the afternoon. Farther N. the Guards, after seizing Hamelin-court, had also established themselves across the main road, and Boyelles and Boiry Becquerelle also fell into the hands of the VI. Corps before the end of the day, which resulted in the capture of 5,000 prisoners and a number of guns.

In view of the success gained during the day, it was decided to renew the advance at 1 A.M. on the morning of the 24th, the moon being then at the full. This decision was fully justified by the excellent results achieved all along the line. On the V. Corps front, it was projected to carry the strong position on the Thiépval plateau by means of a converging attack from S. and W. by the two wings of the 38th Div. While the right brigade stormed the high ground of La Boisselle and Oviviers, the left brigade, wading across the Ancre at Hamel under cover of its detachments thrown over the previous day, pushed forward as far as Pozières, thus turning the defences of Thiépval from the north. In the after-

noon and evening the V. Corps, of which the central and left Divs., the 17th and 21st, had pushed forward through Grandcourt, by dint of heavy fighting, attained the general line W. of Contalmaison-Martinpuich-Courcelette. The IV. Corps had also been highly successful; the 42nd Div. pushed its front by way of Miraumont, where the enemy resisted with unusual stubbornness, to Pys, while the 5th, New Zealand, and 37th Divs., farther N., advanced to the line Grevillers-Avesnes-W. of Behagnies-Mory. The VI. Corps on the left of the army occupied St. Leger and Henin-sur-Cojeul but were held up by a determined defence in front of Croisilles and in St. Martin-sur-Cojeul.

The attack was vigorously pushed on the 25th despite the fact that the troops were becoming weary and the enemy's line heavily reinforced, showed signs of stiffening. The main advance was in the centre; the V. Corps on the right advancing over the old battlefields of 1916 where the ground afforded good facilities for the defence could get on but slowly, and the enemy's prepared fortifications gave him every advantage in the VI. Corps area, where little progress could be achieved. In the centre however, N. of Bapaume, the IV. Corps cleared up the hostile resistance at Sapignies and Behagnies and pushed on in the evening to the line Favreuil-Mory, thus seriously menacing the line of retreat of the defenders of Bapaume.

In fact, at this moment the situation on the front of the XVII. German Army was regarded as "extremely critical." It was believed that the offensive against it was bound to continue and the difficulty of getting up reserves and supplies was enhanced by the lack of communications across the desolated area of the old Somme battlefields. The Army Group of von Boehm was accordingly instructed to retire the line of the XVII. Army to a position already reconnoitred and partly prepared running from Quéant E. of Bapaume and Comblès. The withdrawal took place at once in accordance with orders, and was completed by the morning of the 27th under cover of strong rearguards which fiercely contested the advance of the British III. Army.

Conclusion of III. Army's Advance (Aug. 26-Sept. 1).—During the 26th the V. Corps gained the fruit of its hard struggles of the previous days in a deep advance over the Somme battleground, which carried it forward to the western outskirts of what had once been the villages of Longueval, Fiers, and Le Sars. The IV. Corps continued to swing round to the N.E. of Bapaume, occupying Beugnâtre, but the garrison of the town still held out. The next few days were taken up with bitter and strenuous fighting along all the front of the army, which grew stiffer as the advancing British drew nearer to the new prepared positions of the enemy. A new British Corps, the XVII. (Ferguson), took over the three left divisions (56th, 52nd and 57th) of the VI. Corps on the evening of Aug. 25, and undertook the hard task of overcoming the German resistance around Croisilles and in the Hindenburg line to the E. Croisilles was not finally secured until the 28th when the enemy garrison, finding its retreat menaced from both flanks, abandoned it early in the morning and from that date for four successive days the XVII. Corps was engaged in to-and-fro fighting in the maze of trenches and dugouts around Bullecourt and Hendecourt which were finally secured by the 52nd and 57th Divs., respectively, on the morning of Sept. 1. The line was established E. of Rencourt by the evening. The part of the XVII. Corps in the brilliant operations of the I. Army against the Drocourt-Quéant line on Sept. 2 does not come within the scope of this narrative.

Further to the S. by the evening of Aug. 29 the Germans, though still holding their ground stubbornly before the VI. Corps, had left Bapaume to the New Zealand Div. of the IV. Corps, and retired before the V. Corps to the eastern edge of the devastated area on the general line Morval-Beaulencourt. Following up their advantage the IV. Corps pressed their advance on Aug. 30 and 31 to beyond Rencourt, Bancourt and Frémicourt, thus rendering it possible for their neighbours on the right and left to resume their progress which had for the moment ceased. While the V. Corps on Sept. 1 drove the enemy from Beaulencourt, Morval and Sailly-Saillies and on the 2nd from Le Transloy, Rocquigny and Barastre, the VI. Corps finally

made itself master of the bitterly contested villages of Ecoust and Vaux Vrancourt and pushed forward to Noreuil. The IV. Corps in the centre, keeping pace with its comrades reached the front Villers au Flos-Bengny on the evening of Sept. 2.

During the 13 days' fighting the 14 divisions of the III. Army had engaged 23 hostile divisions, taken from them 11,000 prisoners, many guns and much material of war, and had driven them back to a depth of from 8 to 13 m. on a front of 20, besides inflicting on them heavy losses in killed and wounded.

*IV. Army's Advance to Upper Somme (Aug. 22-30).—*It has already been stated that the left of the IV. Army N. of the Somme had successfully cooperated in the main advance being carried out by the III. Army on its left during all the period under review from Aug. 22 onward. At the same time, other offensive operations were also carried out by the centre and right of Gen. Rawlinson's line astride and S. of the river, which had the effect towards the end of Aug. of forcing the Germans to retire to the line of the Somme above Péronne.

The attack of the III. Corps, delivered on the morning of Aug. 22, had for its objective the capture of Albert and the crests E. and S.E. of it in order to afford a crossing-place for the V. Corps (the right corps of the III. Army) over the Ancre valley. The 18th, 47th and 12th Divs., as also the 3rd Australian Div., were entrusted with the operation, which involved an advance of some 2,000 to 3,000 yd.; the 58th Div. was held in reserve. Despite the fact that all the precautions taken failed to ensure secrecy and that hostile counter preparations began at 4 A.M., 45 minutes before the attack was timed to commence, considerable progress was made on the whole front. The 18th Div. cleared Albert and joined hands E. of Méaulte with the left of the 12th Div., which together with the 47th on its right, had reached practically all its objectives before noon. The 3rd Australian Div. on the extreme right of the attack had also fulfilled their allotted task as early as 8:30 A.M. But in the afternoon a heavy German counter-attack, put in against the centre of the new British line, recovered much of the lost ground in that quarter, and inflicted such severe losses on the 47th Div. that it had to be relieved during the course of the next day by the 58th Div. from reserve.

This untoward incident somewhat disarranged the army plan for the 23rd, which had originally involved an advance on the whole front from Albert to Chaulnes. It was now decided that only the 18th Div. on the extreme left of the III. Corps should attack in conjunction with the Australians S. of the Somme. Accordingly, on the morning of the 23rd, the 18th Div., acting together with the V. Corps of the III. Army on its left, completed its operations of the previous day by the capture of the ridge immediately E. of Albert. The Australian attack to the S. was more ambitious and equally successful. It was carried out on a front of 4 m. by the 32nd Div. on the right and the 1st Australian on the left and involved an advance of some 2,000 yd. in depth, right up to the edge of the area laid waste in 1916, on the approximate line Herleville-Chuignes-Cappy. The divisions debouched at 4:45 A.M., assisted by 45 tanks and covered by an excellent barrage. The 32nd Div. early seized Herleville and the 1st Australian Div. also successfully carried out the first two stages of its advance, but met with unexpected difficulties in the last phase, which were only overcome after severe and gallant fighting. As a result of the day, 9,000 prisoners and 23 guns remained in the Australian Corps' hands.

Gen. Rawlinson decided, as a result of the day's operations, to go on with the attack N. of the river, and by way of variation to the usual methods an advance was carried out just after midnight of the 23rd by the whole of the III. Corps (47th, 12th and 18th Divs.) and the 3rd Australian Division. With the aid of the brilliant moonlight, good progress was made by all these formations, and despite violent hostile reaction, the ground lost on the 22nd was entirely recovered and La Boisselle, Hécordel and Bray all taken and held. The same good success attended the continuance of the advance next day, Fricourt and Mametz being both seized.

It had by now become evident, in fact, that the German re-

sistance on the IV. Army front, partly owing to the vigorous pressure exercised throughout the last four days, partly owing to the successes of the III. Army farther N., was beginning to weaken, and that only strong rearguards were being encountered fighting to gain time for the retirement of the main body behind the line of the Somme above Péronne. The German Higher Command, as already mentioned, on the 25th, ordered von Boehm (who had about the middle of Aug. been appointed to the command of a new Army Group consisting of the II., XVIII. and XI. Armies, between the Ancre and the Aisne) to fall back to the line of the river Somme-Ham-N.E. of Noyon, and the movement was carried out on the 26th and 27th. During these days the progress of the IV. Army was rapid, being opposed mainly by long range artillery fire and strong machine-gun detachments. By the evening of the 27th the Australian Corps, which had handed over part of its line, as far N. as beyond Lihons, to the French I. Army on the night of the 24th, had reached the front Vermandovillers-Fontaine-Vaux, while the III. Corps which had been severely tested by the resistance of three fresh enemy divisions newly put into line on its front had cleared Trones Wood and Longueval. The German II. Army had now reached its chosen positions of defence between Morval and Pargny but had apparently, at the desire of the Army Group which considered it important to retain the possibility of flanking movement from in front of Péronne against any eventual British advance in the open country to the N., decided to retain its hold on the W. bank of the river in that quarter. Accordingly, the resistance in that area, where the left of the Australian Corps was operating, grew stiffer during the 28th and 29th; while the 32nd Div. on the right of the corps reached the W. bank of the Somme astride the Amiens-Brie road without severe fighting early on the 29th, the 5th and 2nd Australian Divs. only established themselves on the river line after heavy fighting and thanks largely to the coöperation of the 3rd Australian Div. on the N. of the Somme. By the evening of the 30th the Australian line ran along the W. bank from Cizancourt in the S. to Biaches and thence over the river to Cléry and was continued by the III. Corps along the western edge of Marrières Wood to Priez Farm and E. of Combles. The Germans in this latter area had also fought stubbornly during the past two days and it became evident that they were here standing on a chosen line of defence. In view, however, of the small prospect of success afforded by any attempt to force the strongly held Somme line above Péronne, the IV. Army Command decided that the next operation must be a strong advance by the centre and left in order to turn that line to the N. and orders to this effect were issued on the evening of the 30th.

*Forcing of the Somme Line by IV. Army (Aug. 30-Sept. 2).—*The plan for the IV. Army's further operations involved the turning of the Somme line, to which the German II. Army had retired, by means of an advance N. of Péronne to the high ground around Nurlu. The III. Corps was to carry out the frontal attack from the W. against the German line northwards from Péronne, while the Australian Corps covered the southern flank of the attack and coöperated in the main operation by pushing forward against Nurlu from the S.W. Before this could be done, however, it was necessary to occupy Péronne and the key to it, the commanding height of Mont St. Quentin. This in itself was a most formidable task, for the position, strong both by nature and by art, dominated all the country to N. and W., and all the river passages by which it could be approached. The German High Command fully realized its importance, and had committed its defence to the picked troops of the 2nd Guard Div. with orders to hold it at all costs.

Sir John Monash, the Australian Corps commander, had already on the 29th formulated his plans for the attack of this stronghold. On this date the line of the corps was held from S. to N. by the 32nd, 5th, 2nd and 3rd Divs., the last-named being N. of the Somme. The idea was to bring over the 5th and 2nd Divs. to the N. bank, for the attack of Péronne and Mont St. Quentin respectively. The seizure of a bridgehead on the N. bank S.E. of Cléry, an essential preliminary, was carried out by the 2nd Australian Div. during the course of the 30th, and the

bridge at Ommécourt was ready for use by before dawn on the morrow. On this same night the 32nd Div. on the corps right extended its front to the N., relieving part of the 5th Div. which in turn took over part of the front of the 2nd Div., thus liberating the necessary forces for the assault.

This was opened at 5 A.M. on the 31st by the 5th Bde., of the 2nd Div. which moved off under cover of a strong barrage and making good progress had attained by 7 A.M. both Feuillaucourt and Mont St. Quentin villages; the right of the brigade however was held up in front of Anvil Wood. To the left of the brigade also the attack of the 3rd Australian Div. had failed to keep pace and a heavy German counter-attack, flung in against the front and left of the troops holding Mont St. Quentin village, compelled them to relinquish it. They rallied again, however, on the western edge and there held their ground till nightfall. Feuillaucourt had also to be abandoned later in the day. Meanwhile the 6th Bde. (also of the 2nd Div.) crossed the river behind the 5th and part of it pushing forward on the right of its comrades, seized Halle and established itself on a line beyond. The remainder halted S.E. of Clery. The 14th Bde. of the 5th Div., also effected a crossing at that place and collected E. of that village, pending the moment when the further advance of the 2nd Div. should allow it to advance against its assigned objective Péronne. By nightfall the 1,200 fighting men of the 5th Bde. had already broken the back of their task. Despite the difficulties which faced them, they had penetrated the formidable hostile positions to a depth of some 2,000 yd., and though reduced in numbers to some 600 rifles had held out on a wide front of 4,000 yd. against reiterated and desperate counter-blows by a foe in every way worthy of their steel. Their single feat of arms was rightly judged one of the finest in the war, and was to receive full fruition on the morrow.

The 6th Bde. of the 2nd Div., assembled S.E. of Clery, was assigned to complete the capture of Mont St. Quentin, passing through the sorely tried 5th Bde., its units already in the front line S.E. of Halle being relieved by the 14th Bde. of the 5th Div., which now undertook the attack on Péronne. While this last-named brigade swept forward through Anvil Wood and Ste. Radegonde, forced its way into Péronne and got possession before noon of practically all the town with the exception of the north-eastern suburbs, the 6th Bde., despite strong opposition from parties of the enemy still at large behind the 5th Bde. front on the Péronne-Bapaume high road, reached the line of that road and after a short preparation by artillery stormed Mont St. Quentin village and wood and established itself on a line from there N. to near Allaines and S. to the E. edge of Péronne. The night of Sept. 1 thus saw the Australian Corps, the 3rd Div. of which on the extreme left had taken possession of the ridges S. of Bouchavesnes, in possession of all its objectives, after completely defeating the enemy opposed to it.

Further to the N. the III. Corps also had done most creditable, if less spectacular work, during these two days of battle. The 58th Div. on the right had cleared Marrières Wood on the 31st, while the 47th Div. made progress towards Rancourt, repulsing a hostile counter-attack. On the morrow these successes were continued and completed by the capture of Rancourt and Bouchavesnes, while the 18th Div. on the left of the corps in a brilliant series of attacks seized in turn Priez farm, Frégicourt and Saillisel, inflicting serious losses on the enemy, who afforded a stubborn resistance.

Sept. 2 saw the completion of the successful operations of the IV. Army in the battle of Péronne, the Australian Corps occupying Allaines and the III. Corps St. Pierre Vaast and Vaux woods. The results of the battle were imposing enough even in mere figures. In the period between Aug. 22 and Sept. 2 the IV. Army's 9 divs. had engaged and defeated 23 hostile divs. and taken from them over 23,000 prisoners, many guns and vast quantities of material. The strong line of the Somme had been turned and rendered untenable by sheer hard fighting in which the attacking troops had shown themselves capable of meeting and defeating the best of the German divisions which, thrown in piecemeal and in the utmost haste and confusion as they arrived

on the field, had been unable to hold for long even the strongest natural and artificial defences.

General Results of the Battle of Bapaume-Péronne.—In the battle described above the British III. and IV. Armies, consisting of five corps (23 divs.) in all, had fought and defeated the German XVII. and II. Armies, consisting of five corps (46 divs.), had forced them to fall back to a depth of from 6 to 13 m. on a front of 28, and had captured from them a total of 34,250 prisoners and 270 guns, without reckoning other material of war too various to recapitulate. The whole area of the Somme battlefields, which had cost the British five months' bitter fighting in 1916, had been conquered in less than a fortnight; more than half the area gained by the great German advance of the spring had been recovered; the only good natural line of defence available for the enemy to the W. of the Hindenburg system had been broken asunder; and the moral and material superiority of the British over the German fighting machine had become patent to the world. (X.)

SONNINO, SIDNEY, BARON (1847–), Italian statesman (see 25.410). During the debates on Giolitti's Steamship Subsidies bill in the spring of 1909 it was Baron Sonnino who conducted the most vigorous attacks against the Government, exposing the radical defects of the measure, and when Giolitti resigned on Dec. 2 it was Sonnino who was called upon to form a ministry, for the second time. But he did not enjoy the favour of the still Giolittian Chamber, and his Cabinet was defeated over the new shipping bill. On March 21 1910 he resigned, again after 100 days of office. He continued to take an active part in the debates in the Chamber, and was a stern but just critic of Giolittian political methods, although during the Libyan war he generally abstained from opposition for patriotic motives. In the autumn of 1914, after the death of the Marquis di San Giuliano, the Premier Salandra assumed the Foreign Office for a short time, but when he reconstituted his Cabinet on Nov. 5 he offered that portfolio to Sonnino, who accepted it. His conduct of the Foreign Office was characterized by sincerity of purpose, high principles, unwavering patriotism and a wide knowledge of international politics. He had not, moreover, a free hand. He was still Foreign Minister, under Orlando's premiership, during the Peace Conference, which he attended as second Italian delegate from Jan. 18 to June 19 1919. On the fall, however, of the Orlando Cabinet (June 19 1919) Sonnino retired into private life. The irritation of the whole of Italy against the policy of the Allies towards Italy at the Peace Conference reacted to some extent against the nation's representatives at Paris, and Sonnino himself came in for a large share of unpopularity, although the more intelligent and better informed part of public opinion realized the great difficulty of his task and the insufficient support afforded him by Orlando, as well as the value of his actual achievements. He did not stand for Parliament at the elections in Nov. 1919, but was subsequently made a senator. In spite of what was regarded as his failure to overcome the obstacles of the Peace Conference, he enjoyed the reputation of being the greatest Minister for Foreign Affairs that Italy had had since Cavour, with the possible exception of Crispi, while as a financier he ranked very high. He was also a man of wide reading and culture, and a distinguished Dante scholar and bibliophile.

SOROLLA Y BASTIDA, JOAQUIN (1863–), Spanish painter (see 25.434), was engaged for practically the whole of the decade 1910-20 on work for the Hispanic Society of America. It includes a series of portraits of Spanish writers, and a "Panorama of the Forty-nine Provinces of Spain" consisting of forty-nine immense compositions, each representing views, costumes and customs of a different province. This great undertaking was completed before paralysis brought the artist's painting to an end. Important exhibitions of his work were held at the Grafton Galleries, London, 1908; in New York, 1909; in Chicago, 1913; and he was represented by two typical works in the 1920-1 Exhibition of Spanish Paintings at Burlington House.

See Hispanic Society of America, *Eight Essays on Joaquín Sorolla y Bastida*, 1909; A. de Beruete y Moret, *Sorolla y Bastida*, 1920.

SOUND (see 25.437).—The increase in our knowledge of the subject of acoustics (the science of Sound) during recent years has been largely associated with the war conditions which prevailed from 1914 to 1918. As a consequence of the war the development of this science has been abnormal,¹ and research has been directed towards the rapid realization of practical acoustic devices and methods for immediate use in warfare, both on land and sea. A general survey of the work done shows that the advances consist of applications of well-established principles, rather than the discovery of new phenomena. Generally, the observations made have proved to be in accordance with previous theoretical investigations, mainly due to the late Lord Rayleigh.² This war work falls naturally under two headings, viz. (1) the detection and perception of direction of sounds in air, and (2) the detection and perception of direction of sounds in water. Theoretically, these two problems have much in common, but, practically, there are important differences which make it desirable to treat them in separate sections. A special section (3) is devoted to the important advances recently made in auditorium acoustics, and the remaining section (4) deals briefly with miscellaneous outstanding features of modern work on sound, not essentially military in character.

I. DETECTION AND PERCEPTION OF DIRECTION OF SOUNDS IN AIR³

Detection.—The human ear itself is a remarkably sensitive detector of the air vibrations which constitute sound. It is still much superior in this respect to any mechanical device which has yet been produced for recording the vibrations visually. Thus the perception of feeble sounds of necessity depends upon the limitations of audibility, either indirect listening, or with the ear aided by the intervention of an electrical device such as a microphone. The audibility of a feeble sound can be very largely augmented by making use of the principle of resonance, provided that the sound itself approximates to a pure tone. This can be secured, for example, by the use of a Helmholtz resonator applied to the ear in the case of direct listening, and in addition, by tuning the diaphragm receiver when microphonic listening is adopted. It has happened fortuitously that one of the chief sounds in air which it is important to be able to detect, viz. those emitted by aircraft, do contain predominant notes which enable the application of resonance, as above indicated, to increase largely the range of audibility. Typical predominant frequencies (apparently due to engine exhaust) are given in the following table, which relates to the engine running at the usual speed:—

Aeroplane engine	Frequency (vibrations per second)
S. E. 5	130
R. E. 8	90
F. E. 2B	70
Avro	90
Gotha	80

¹ Owing to the abnormality of the conditions, it is impossible to follow the usual practices in writing the present article. Experiments on sound, with military ends in view, have been carried out in nearly all the belligerent countries. Comparatively few of the results have found their way into the recognized scientific journals, largely by reason of the secrecy which is still frequently enforced by the various Governments, under whose control most of the work was done. In the circumstances it is not safe to attempt to assign credit to particular investigators, nor is it possible to give adequate references. The present article has been drawn up, therefore, upon broad general lines which, since they fulfil censorship conditions, form necessarily a by no means complete survey; and names have been avoided as far as possible.

² Lord Rayleigh's work is contained in his *Collected Papers* (No. 6, 1920). His contributions were numerous between 1911 and 1919, when he died.

³ The information contained in this section is largely drawn from a manual entitled *Development of Sounds*, kindly placed at the writer's disposal by the British Munitions Inventions Dept.

The following frequencies have been detected in the sounds from the Maybach engines of a Zeppelin airship:—

Slow speed—27, 54, 108, 135, 243.
High speed—57, 114, 171, 228.

The operation of the *Doppler effect*, arising from the relative motion between the aircraft and the observer, prevents the possibility of the identification of the machine by means of the observed frequency, this being liable to change by as much as 20%, according to the speed and direction of flight. An interesting observation which has been constantly made is that the notes of low pitch continue to be heard at ranges where those of high pitch have ceased to be audible. This is in accordance with the theoretical expectation that damping increases with frequency.

The determination of the direction whence a sound arrives is theoretically possible by a variety of methods dealt with below, several of which have been tried in aircraft localization.

(a) *Binaural Listening.*—Lord Rayleigh's experiments (*Collected Papers*, vol. 5, p. 347) have shown that low-pitched sounds are determined in direction by the observation of the phase difference between the vibrations arriving at the two ears. This principle has been applied in direction-finding, and the effect has been exaggerated by increasing the distance between the two points of reception. The sound is received by two equal trumpets or horns rigidly connected together and capable of rotation about an axis perpendicular to the line joining them. Separate and exactly equal tubes lead from the trumpets to the two ears, respectively, and the apparatus is rotated until the sound under observation appears to come from directly in front. The line joining the sound receivers is then perpendicular to the incident sound stream. An alternative method which dispenses with the necessity of rotating the apparatus is to use a *compensator* or *phase-measurer*, which consists of tubes, adjustable in length, inserted between the sound receivers and the appropriate ears, so as to provide a path difference equal to that between the distant source of sound and the two receivers. Adjustment of the tube lengths is made until the impression received is that the sound is neither to the right nor to the left, and the determination of direction is then a matter of simple geometry. In practice the compensator is graduated to give direct angular readings.

The practice of binaural listening has verified theoretical conclusions in several important respects. It has been found that it is easier to perceive the direction of a mixed sound, or noise, than a pure note. Apparently it is necessary that the wave train should contain more or less isolated special characteristics whereby the phase difference can be readily appreciated. In the regular sine wave corresponding to a pure tone each vibration is exactly like those which immediately precede and follow it, and the ears are unable to identify corresponding displacements. It is apparently also necessary for successful binaural listening that the two portions of the incident wave which enter the two receivers should be free from subsequent distortion; in particular, that the sound receivers should be as nearly as possible non-resonant for the vibrations in question. Any amplification of the sound which depends upon resonance, therefore, such as the use of Helmholtz resonators already referred to, is incompatible with efficient direction-finding by observations of phase difference.

The construction and arrangement of the receivers used has varied very much in practice. As a typical system, that commonly used in the British army may be quoted, namely, circular cones, 2 to 4 ft. long and of semi-angle 20°, as receivers, placed about 7 ft. apart—a distance which proved to be sufficient for attaining nearly the maximum practical accuracy of setting.

The method is subject to many errors, chiefly those arising from the motion of the sound source, refraction due to temperature inequalities in the air, and the effect of winds. The necessary corrections are tabulated for use in practice.

(b) *Sound Mirrors.*—Some success has been attained in direction-finding by means of concave sound reflectors. The chief limitations have arisen from the question of size, and, consequently, of

⁴ This method of perception of direction has been largely used also in a connexion which scarcely justifies treatment in a separate section. The *geophone* is an instrument for direction-finding of sounds proceeding through the earth, and its particular use during the war was for localizing the sounds of picks, etc. used in tunnelling and land mining. It consists of two hollow boxes connected by equal tubes to a stethoscope arranged so that the sounds proceed from the two boxes to separate ears. The boxes are laid upon the ground a few feet apart, and moved about until the sounds of the pick appear to come from straight ahead. It is then known that the sound source is on a line perpendicular to that joining the two geophone receivers, since the sounds arrive through the earth in synchronism. By combining several pairs of geophones separated by considerable distances, the actual position of the pick can be estimated, for it lies at the intersection of the several perpendiculars above specified.

portability. In optics the size of mirrors commonly in use is very great in comparison with the wave-lengths of the light; in the corresponding problem in acoustics it is almost impossible to make them so; and yet this is a necessary condition for the geometrical laws of reflection to apply with accuracy. In the largest sound mirror—perhaps 20 ft. in diameter—the size is at most only a few wave-lengths for the aircraft sounds under investigation, with the result that the image of a distant sound obtained at the focus proves to be an area much larger than that corresponding to optical calculations. There is therefore no advantage secured by making the mirror paraboloidal instead of spherical, and considerable roughness of the surface is not detrimental. The mirrors were usually made of concrete, and listening was effected either by means of a small horn receiver placed in the focal plane and connected by a tube to the ears, or by means of a microphone placed in a similar position. If, as was more usual, the mirror was fixed, the direction of the sound source could be found by determining the position of maximum intensity in the focal plane. It may be noted that in this method of direction-finding amplification is obtained on account of the area of the mirror, and that further augmentation is attainable by using resonators, to which the same objections do not apply as in binaural listening. The accuracy of the determinations vary very much with frequency, being much greater for notes of high pitch than for low, as would be anticipated from considerations of wave-length.

(c) *Interference and Diffraction Methods.*—There have been many attempts to apply the principle of interference as a substitute for binaural listening, *i.e.*, by ultimately mixing the sounds entering the two receivers, instead of leading them to different ears, and adjusting the compensator until the total sound heard is as loud as possible. Theoretically this will occur when there has been provided in the compensator a difference of path equal to the path difference outside the receivers. The method has not proved very successful, for a variety of reasons, some of which are obscure. We shall not elaborate them here.

On the other hand, remarkable results have been obtained by the application to sound waves of a phenomenon well known in the diffraction of light. A small distant source of light gives in the middle of the shadow of a small circular obstacle a luminous region, called the "white spot," arising from the diffraction of light round the edges of the obstacle. The same phenomenon is observable in sound under suitable conditions. Thus a large horizontal disc, at least 20 ft. in diameter, and made of material which either reflects or absorbs sound, will give below itself a sound shadow of a sound source, such as an aeroplane, above it. Near the centre of the shadow, in a position depending on that of the source, there is a region where the sound heard is comparatively loud—in many cases much louder than it would be if the disc were absent. The relation between the direction of incidence of the sound and the position of maximum intensity has been calculated, and the method provides, perhaps, the most reliable means of perceiving the direction of air-borne sounds.

(d) *Sound Ranging.*—This special military aspect of the localization of sound sources, *viz.* those arising from gun-fire and shell bursts, is dealt with in the article RANGE-FINDERS.

2. DETECTION AND PERCEPTION OF DIRECTION OF SOUNDS IN WATER¹

Of all the methods practised for the detection of submarines that depending on the sounds which they emit has been of the widest application. The question of detection has been, of course, of nearly equal importance in the opposite sense, *viz.* the hearing of surface ships by the crew of a submerged submarine. The sounds created in the sea by a screw-propelled ship are of a very complicated character, arising partly from the interaction between the propeller and the water, and partly from the vibrations of the machinery which are transmitted through the walls of the ship into the sea. They vary greatly from ship to ship, even of the same class; and, in the later stages of the war, submarines had been constructed which, when cruising submerged at certain slow speeds, emitted practically no noise at all. In many ways the detection of submarines in the sea is more difficult than that of aircraft in air. Normally, listening in air takes place at stations which are fixed; in submarine listening the stations were most frequently ships, which for tactical reasons connected with their safety, had to be constantly on the move. Their own machinery noise and the acoustic disturbances arising from their motion through the water were very

apt to drown the noises proceeding from more distant sources. The noise of the sea, too, even in weather not at all stormy, interfered greatly, and the range at which a submarine could be heard varied much from day to day. A serious additional limitation was that recourse could not normally be had to the reflection of ordinary sounds (as is possible in air) chiefly by reason of the great size of the necessary reflectors. For the speed of sound in sea water is more than four times that in air, so that the wave-lengths are larger in the same ratio. This necessitates a corresponding increase in the linear dimensions of the sound mirror, if equal efficiency is to be obtained.

Hydrophones.—Hydrophones, or under-water sound detectors, were already in use before the war for signalling purposes, being carried by ships for listening to submarine bells operated by Trinity House as warnings in foggy weather. They consisted of small, metal, water-tight cases of which one face was a metallic diaphragm operating an enclosed microphone. The electrical disturbances of the microphone caused by any vibration of the diaphragm arising from sound pressure waves in the sea, were conveyed to telephone receivers on the ship, where listening took place. It was usual to suspend the hydrophones in water-filled tanks attached inboard to the outer shell of the ship, which, owing to the fact that steel in water transmits sound almost completely, does not diminish appreciably the intensity. Normally the hydrophone diaphragm was tuned so that its natural frequency in water² approximated to that of the signalling bell, and so that increased range could be secured by depending on resonance.

The earlier hydrophones used for naval purposes were of much the same type, although the resonant diaphragm proved to be by no means an unmixed advantage. All sounds containing a component corresponding to the diaphragm frequency were distorted in reproduction, and what was gained in sensitivity was liable to be lost in the difficulty of recognition, or, in other words, failure in discrimination between genuine noises due to a submarine and other noises inevitably present in the sea. Appeal to resonance is only really advantageous when the sound under observation has a predominant note, as in the case of an aeroplane; and submarines do not display this characteristic. Ultimately hydrophones of a non-resonant character came to be preferred, and were frequently used in practice. These consisted most usually of enclosures made of rubber, sufficiently thick to withstand the pressure of the sea at the usual depth (about 15 ft.), and having natural frequencies below the limit of audition.

An alternative type of hydrophone consisted merely of a hollow enclosure without a microphone, sometimes with a metallic diaphragm, and sometimes simply a rubber tube, filled with air and connected by long tubes to stethoscopes applied to the ears. These are operated by the transference of the pressure vibrations from the sea to the air cavity and thence to the ears. Electrical hydrophones have the advantage over non-electrical ones that their sensitivity can be readily augmented by various means, *e.g.*, by the use of thermionic amplifiers (*see* WIRELESS TELEGRAPHY).

In cases where the hydrophones had to be used by ships in motion, they were sometimes fitted into the hull of the ship; or themselves consisted of fish-shaped bodies towed at a considerable distance behind the ship. The former precaution, *i.e.* making the shape stream-line, aimed at diminishing the vibrations created by the passage of the hydrophone through the water; the latter had in view the partial elimination of the disturbances arising from noises in the towing ship. Even so, it frequently became necessary to stop the engines temporarily, and listen with the towed hydrophones while the momentum of the ship continued to carry it forward. This proved to be only feasible at comparatively slow speeds.

Directional Hydrophones.—All the hydrophones so far described are of a non-directional character, *i.e.* the intensity of the sound heard in them is practically independent of the orientation of the sensitive receiving diaphragm with respect to the position of the source of sound. The limitations of dimensions necessitated by considerations of portability, etc., are such as to render the instruments much too small to give an effective "sound shadow." The reason for this has already been mentioned, *viz.* the great wave-lengths corresponding to audible sounds. At a frequency of 500 per second, for example, the wave-length in water is nearly ten feet.

Differential Hydrophones.—Curiously enough, however, one type of directional hydrophone, called here for distinguishing purposes a *differential* hydrophone, did, in fact, depend upon the small differences of pressure operating upon its two sides; and it met with considerable success. It was made in various forms, the simplest of which consisted of a circular metal diaphragm, bearing at its centre a water-tight box containing a microphone, and clamped round its rim to a heavy metal ring. When placed in the sea so that the plane of the diaphragm passed through the position of the sound source, the pressure variations on the two sides are the same both in amplitude and phase, with the result that the diaphragm and therefore

¹ The following publications should be consulted, although, for reasons already given, they form by no means adequate references:—H. C. Hayes, *Engineer* (1920), p. 491; C. V. Drysdale (Kelvin Lecture), *Journ. I.E.E.* (1920); W. H. Bragg, "Submarine Acoustics," *Nature*, July 1919; F. L. Hopwood, "Submarine Acoustics," *Nature*, Aug. 1919.

² This is considerably lower than the natural frequency in air, on account of the additional loading by the water.

the microphone, has no motion imparted to it, and the sound heard is a minimum. If, however, the diaphragm faces the sound source, there are, apparently, differences in the pressures on the two sides (probably in both amplitude and phase), and a small differential vibration takes place, with consequent sound in the receiving telephone. Actually, as the hydrophone is rotated through 360° about a vertical axis, two maxima and two minima of sound intensity are observed. In this form, therefore, the instrument is what is called *bi-directional*, i.e. it is unable to distinguish between sources in *front* and *behind*. The desirability of obtaining a *uni-directional* instrument led to the introduction of the so-called *baffle-plate*, the behaviour of which has not yet been explained satisfactorily in terms of orthodox theory. The essential characteristics of a baffle appear to be that it should be made of non resonant material and have air cavities within it. Such a plate, fixed at a small distance (which has to be determined by trial) from one face of a bi-directional hydrophone, transforms it into a uni-directional instrument. A single sound maximum is now obtained upon rotation, occurring when the sound source and the baffle plate are on opposite sides of the diaphragm; and a single minimum,—this when the baffle lies between the sound source and the diaphragm. The "edge-on" minima, observed when the baffle is absent, now disappear.

Binaural Listening.—The principles underlying this method of direction-finding have been described already. In the present case the main difference is that the sound receivers have to be submerged hydrophones. It has been found to be equally necessary for success that these should be as completely as possible non-resonant. The simplest arrangement used in practice was two rubber cavities placed several feet apart horizontally, and joined by separate equal tubes to the two ears. The device could be rotated about a vertical axis, usually passing through the hull of the operating ship. As in the case of air listening, compensators were often used in order to avoid the necessity of rotating heavy apparatus. An arrangement much preferred was to tow two or more fish-shaped hydrophones in known positions (about 12 ft. apart) behind the ship. Here electrical transference of the acoustic disturbances had to be adopted, and this necessitated great care in the choice of the microphones and telephone receivers so as to avoid selective resonance. (The behaviour of microphones in this respect was often unsatisfactory, and telephone earpieces, or magnetophones, were frequently substituted for them. This results in diminished sensitivity, but the binaural effects are much improved.) The telephone receivers delivered the sound into the compensator, and the phase difference was measured in the usual way; allowing, of course, for the difference of speed of sound in the sea and in the air channels of the compensator. In using a compensator with two sound-receiving units only, there remains an ambiguity of estimated direction, i.e. one cannot distinguish between the angles θ and $\pi + \theta$. The introduction of a third unit, so that the three form a triangle of known dimensions,—the units being capable of use in pairs with the compensator—ensures the correct choice between the alternative angles.

Other Methods of Direction-finding.—Several other methods of perception of direction, not easy to classify, have found application in practice. One of these consisted in fitting in the shell of a ship, on opposite sides, two diaphragms with microphones attached, arranged so that the hydrophones thus formed were of as nearly as possible equal sensitivity. These were listened to alternately by means of a reversing switch. The ship, on account of its considerable size, was capable of giving a marked sound shadow. Thus the starboard hydrophone would give greater response than that on the port side if the sound source were to starboard, and vice versa. By steering the ship so that the responses were equal, it could be inferred that the course was directed towards the cause of the sound. The limitations of the method were mainly those arising from local noises; and the speed had to be small while listening took place.

In other cases large numbers of sound receivers, usually simple diaphragms whose function was to transfer the vibrations from the sea to the air inside, were inserted in the ship's hull. Good results were obtained by an arrangement of this kind, called the Walser gear, in which the sound receivers were disposed at regular intervals on a large bulge, in the shape of a spherical segment, incorporated in the hull on either side towards the bows. The system acted as a sound lens, a sound focus occurring at a point where the "sound paths" by alternative routes were equal. Application of the laws of geometrical optics enabled the relation between the position of the focus and the direction of incidence of the sound wave on the ship's side to be determined.

Sea Sound-Ranging.—The methods hitherto mentioned for perceiving sound direction would all fail when the sounds are abrupt in character, because they all require an appreciable time for carrying out the necessary tests. To determine the position of an exploding submarine mine or torpedo we require, therefore, a different device. A suitable method is one identical in principle with that practised on land. The main variations in applying the device to the sea are that the microphones must be in submerged hydrophones, and that a correct knowledge of the velocity of sound in sea water must form the basis of the calculations. Ordinary non-directional hydrophones of the type first mentioned have proved to be quite sufficiently sensitive. Indeed, the greatness of the distances at which explosions in the sea have given unmistakable im-

pressions on the recording film has been surprising. Small detonators serve at distances of several miles, while the explosion of 40 lb. of gun-cotton is operative more than 100 m. from the receiving hydrophones. Many experiments have been carried out by the British Admiralty with hydrophones disposed in suitable positions on the East coast of Britain, and the installations promise to be useful, not only for locating mine and torpedo explosions in circumstances of war, but also for navigational and surveying purposes. A ship in fog, for example, could ascertain its position by exploding (with due notification by wireless to the sound-ranging station) a small charge near itself in the sea; the station could within a few minutes inform the ship—again by wireless—of its position.

Sea sound-ranging has necessitated the accurate redetermination of the velocity of sound in sea water. This has been accomplished by the inverse of the process just mentioned, viz. by exploding charges in the sea, and measuring by the recording string galvanometer the time intervals between the reception of the first shock by hydrophones submerged in accurately known positions. The observed velocity depends on several factors, including tidal flow, temperature, and salinity, which vary from place to place. The following table gives some of the results obtained, corrected to a standard salinity corresponding to a specific gravity of 1.026 and a temperature of $10^\circ\text{C}.$ —

Date	Place	Corrected Velocity in ft. per sec.
16. 5. 18.	Dover	4,882
6. 11. 18.	"	4,921
18. 7. 18.	"	4,924
26. 7. 17.	Culver (l. of W.)	4,962

The effect of tide, apparently, has not been allowed for. It would amount, at most, to a few feet per second.

3. AUDITORIUM ACOUSTICS

The acoustics of public buildings have recently been put on what approximates to an exact scientific basis, largely as a result of the work of W. C. Sabine (*Frank. Inst. J.*, 170, p. 1, 1915). For good hearing three conditions are necessary and sufficient. The sound heard must be *loud enough*; the simultaneous constituents of a mixed sound must preserve their *relative intensities*; and the successive sounds must *remain distinct and in the correct order*, and be free from extraneous noises. The extent to which these conditions are fulfilled depends on the construction of the auditorium, its shape, its dimensions, and the materials of which it is composed. In already finished buildings radical alterations of the first two are not often feasible, but great improvements can be secured solely by suitable changes in the internal features.

The main difficulty arises from what has been called *reverberation*, due to the multiple reflection of sound at different parts of the room. If the reverberation is prolonged, it means that the rate of absorption of the sound is slow. Thus, in a lecture room at Harvard, where these experiments were commenced, the rate of absorption was so small that a single spoken word continued to be audible for $5\frac{1}{2}$ seconds. Successive syllables thus had to be heard and appreciated through a loud mixed sound due to the reverberation of many previous syllables, and the conditions of hearing were intolerable. Great reduction of the multiple echoes constituting reverberation can be made by increasing the rate of absorption of sound. It is apparent that, in the space of several seconds, the sounds travelling at 1,100 ft. per sec. will have suffered many successive reflections, and will, therefore, have penetrated to practically all parts of the room. The sound will have become diffuse radiation, and absorbing material introduced almost anywhere will be equally effective in reducing reverberation. An open window proves to be a complete absorber, in the sense that it permits the egress of the maximum possible quantity of sound radiation (*cf.* the properties of a small aperture in an isothermal enclosure in heat radiation). The introduction of cushions, carpets, wall hangings and people also largely diminishes reverberation, because of their considerable absorbing powers. Sabine has made a systematic study of the coefficients of sound absorption of various materials by the inverse method of measuring their effect in reducing the duration of reverberation. Typical results are given in the following table. These apply to the frequency an octave above middle C.

Material	Coefficient of Absorption
Open window	1.000
Linoleum, loose on floor	0.12
Oriental rugs	0.29
Plaster on wood lath	0.034
Glass, single thickness	0.027
Plain ash chairs	0.008
Upholstered chairs	0.30
Hair felt, 2.5 cm. thick, 8 cm. from wall.	0.78

Other measurements indicated that an audience gave an absorption equal to 44% of that due to an equal area of complete absorber, thus accounting for the improved hearing conditions known to exist in well-filled buildings.

The absorption of sound can thus be adjusted with precision, but it must not be carried too far, otherwise the sound intensity is too much diminished. The ear is able to disregard, or even to take advantage of, reverberation which is not too prolonged, and the extent of absorption has to be adjusted to the appropriate amount. Too many apertures such as open windows or doors must be avoided.

Sabine has also made examination of the exact manner in which sound is reflected in an auditorium by constructing scale models of the latter, and photographing the sound waves at various instants after creation, using the beautiful method due to Toepler (*Annalen der Physik*, 127, p. 556) and elaborated by R. W. Wood (*Physical Optics*, 2 ed., 1911, p. 94). By this means the positions of the sound waves, both incident and reflected, are capable of observation at all instants and at all points in the model room, and they provide data upon which can be based correct architectural construction from the acoustic point of view.

4. MISCELLANEOUS ADVANCES

Absolute Measurement of Sound.—A. G. Webster (*Nat. Acad. Sci. Proc.*, 5, p. 173, 1910) has advanced to a considerable extent the methods of absolute measurement. For this purpose it is impossible to rely upon audition, handicapped as it is by the vagaries of the ear. What is required is a reliable mechanical device, the performance of which is constant, to record the sound vibrations with sufficient magnification. Webster has made an exhaustive study of the properties of various materials, and has constructed from those most suitable for the purpose two instruments which he has called the *phone* and *phonometer* respectively. The phone provides a means of creating a simple tone of intensity and frequency which are under control and capable of exact measurement. The phonometer is an instrument for measuring absolutely the vibrations received by it. It consists of the combination of a diaphragm and a resonator, both of which are adjustable in frequency. The motion of the diaphragm is observed by making it a reflector and part of a Michelson interferometer, so that the amplitude is measured in terms of the wave-length of suitable monochromatic light. In practice the interference fringes are photographed on a moving film upon which they appear as wavy lines. Against this instrument, which is regarded as a standard, other portable phonometers can be calibrated, these depending on the simpler process of the deflection of a beam of light set into angular oscillation by the receiving diaphragm. With such instruments, and also with D. C. Miller's *phonodeik* (referred to later) L. V. King has carried out an elaborate investigation on the propagation of sound in air and fog-signal efficiency (*Phil. Trans.*, 218, p. 211, 1919) in the region near Father Point, Quebec. King, in this paper, also describes a modification of the siren called the *diaphone*, used as a standard source of sound in his research.

Analysis of Sound.—Webster's phonometer described above is a resonant instrument, and, therefore, unsuitable for the analysis of mixed sounds. Much progress has been made, however, in the analysis of such sounds, using non-resonant recorders, for example, D. C. Miller's *phonodeik*. This instrument, which depends on the motion imparted to a tiny mirror by the opera-

tion of a vibrating diaphragm, is described in Miller's *Science of Musical Sounds* (1916), where also will be found the results of the analysis of various sounds. Similar work has been carried out by C. V. Raman, in relation to the vibrations of bowed strings and instruments of the violin family (*Indian Assoc. for Cultivation of Science*, Bull. No. 15, 1918). In these cases the sound record is of the ordinary type and consists of the trace on a moving photographic film of a spot of light vibrating at right angles to the motion of the film, thus forming a transverse wave. Records of a different type have recently been obtained (A. O. Rankine, *Proc. Phys. Soc. Lond.*, 32, p. 78, 1919) in which the sounds are caused to vary the intensity of a narrow beam of light, which gives on a moving film a line image perpendicular to the motion. The record thus consists of a negative film of varying transparency along its length. It is not so suitable as transverse records for direct analysis of the component frequencies, but it has the advantage that it admits of reproduction of the sound by means of a selenium cell, such as is used in phototelephony. This arrangement constitutes a novel type of phonograph operated by light, first invented by Ernst Ruhmer in 1900, but hitherto little known. (A. O. R.)

SOUTH AFRICA (see 25.463).—On the conquest of German S. W. Africa by the Union forces in 1915 the whole of S. Africa, except for the Portuguese possessions S. of the Zambezi came under British administration. Excluding the Portuguese territory (for which see DELAGOA BAY and PORTUGUESE EAST AFRICA), S. Africa was in 1921 divided politically as follows:—

1. The Union of S. Africa, a self-governing dominion of the British Empire formed in 1910 and consisting of the former colonies of the Cape, Natal, Orange River (Free State) and Transvaal.
2. The S. W. Protectorate (ex-German S. W. Africa), administered under mandate as an integral part of the Union.
3. The native protectorates of Basutoland, Bechuanaland and Swaziland, administered by the British Colonial Office.
4. Rhodesia, consisting of two separate administrations, S. Rhodesia and N. Rhodesia; both under the rule of the British S.A. Company.

Area and Population.—Including both Rhodesias the area of S. Africa is approximately 1,650,000 sq. m., of which some 125,000 sq. m. are Portuguese. The total pop. in 1921 was little over 11,000,000, of whom some 700,000 lived in Portuguese territory.

The following table shows the white population in the Union and in Rhodesia at the censuses of 1911, 1918 and 1921:—

	1911	1918	1921
Union of S. Africa	1,276,242	1,421,781	1,521,635
S. Rhodesia	23,606	..	33,621
N. Rhodesia	1,497	..	3,585
Total	1,301,345	1,421,781	1,558,841

The increase per cent. in the Union in the period 1911-21 was 19.23, masculinity (the number of males to 100 females) decreased from 115.92 to 100.14.

The next table gives particulars of area and pop. of British South Africa at the 1911 census:—

	Area Sq. m.	Pop. 1911 White	Native and Coloured	Total
Union of S. Africa:				
Cape Province	276,995	582,377	1,982,588	2,564,965
Transvaal Province	111,196	420,562	1,265,650	1,686,212
Natal Province (includes Zululand)	35,371	98,114	1,095,929	1,194,043
Orange Free State Province . .	50,392	175,189	352,985	528,174
Total Union	473,954	1,276,242	4,697,152	5,973,394
Territories:				
S. Rhodesia	148,575	23,606	747,471	771,077
N. Rhodesia	290,000	1,497	821,102	822,599
Total Rhodesia	438,575	25,103	1,568,573	1,593,676
Protectorates:				
Bechuanaland	275,000	1,692	123,658	125,350
Basutoland	10,293	1,411	402,434	403,845
Swaziland	6,536	1,083	98,876	99,959
Total Protectorates	291,829	4,186	624,968	629,154
Total British S. A.	1,204,358	1,305,531	6,890,693	8,196,224

Compared with the census of 1904 the increase in the white pop. was 172,399. Of this increase 123,285 was in the Transvaal. In Rhodesia the white pop. had nearly doubled in the seven years. The increase in the native and coloured pop. was 885,660. With respect to the coloured pop. two important factors must be remembered. (1) The Cape province total of native and coloured includes 391,000 persons with a marked strain of white blood, officially classed as "mixed"; the total "mixed" pop. being 435,000. (2) The Natal province total of native and coloured includes 133,000 Indians. There were also 10,048 Indians in the Transvaal, the total Asiatic pop. being 152,000.

The following table gives particulars of the white pop. of the Union by provinces at the censuses of 1911, 1918 and 1921:—

	1911		1918		1921	
	Males	Females	Males	Females	Males	Females
Cape Province	301,208	281,109	311,312	307,513	329,934	321,620
Natal	52,495	45,619	62,745	59,186	70,624	66,834
Transvaal	236,913	183,649	260,840	238,507	284,952	258,529
O. F. S.	94,488	80,701	93,969	87,709	97,971	91,171
Total, Union	685,104	591,078	728,866	692,915	783,481	738,154

The coloured pop. of the Union in 1921 was in round figures 6,000,000, that of S. Rhodesia 744,000 and of N. Rhodesia about 1,000,000, that of the native protectorates 750,000, that of S.W. Africa 240,000, or a total of about 8,750,000.

There were in 1918 five towns with a white pop. of over 20,000 and eight towns with a white pop. between 10,000 and 20,000. The following list of the five chief towns gives the total pop. at the 1911 census with the white pop. in 1918 in brackets:—Johannesburg 237,104 (137,166), Cape Town 161,759 (99,683), Durban 89,998 (48,413), Pretoria 57,074 (41,090), Port Elizabeth 37,063 (23,339). Outside the Union the only considerable towns in S. Africa were Bulawayo and Salisbury in Rhodesia, Swakopmund and Windhuk in the S.W. Protectorate and Lourenço Marques (Delagoa Bay) and Beira in Portuguese territory.

THE UNION OF SOUTH AFRICA

The Union of S. Africa came into being on May 31 1910. Minor amendments were made in the constitution during the next 10 years, but its main features (*see* 25.467) remained unaltered. In accordance with the electoral provisions—the basis of representation being the number of European male adults as ascertained by census taken every fifth year—the Transvaal province obtained nine additional seats in 1915, and four more seats were added in 1920. The seats allotted in 1920 were Cape 51, Transvaal 49, Natal and Orange Free State 17 each.

No alteration was made in the franchise laws. In the Cape province in 1919 out of a total of 186,000 voters, 33,000 were "other than European." In Natal the voters numbered 32,000, of whom 348 were "other than European." In the Transvaal (140,000 voters) and Orange Free State (47,000 voters), "Europeans" only, possess the franchise.

Agriculture—The progress made in agriculture (including pastoral occupations) was in many respects the most encouraging feature in the economic development of S. Africa between 1910–21. The establishment in the Transvaal during the period of Crown Colony Government, of an agricultural department on scientific lines had given an impetus to the adoption of modern methods by the farmers, and the fusion, at the Union, of the agricultural departments of the four former colonies led to greater improvements. By withdrawing the control of agriculture from the provinces the Union Government was able to co-ordinate the work and to disregard artificial boundaries. Much of the progress was due to Gen. Botha "who with his instinct for things that really mattered" had held the portfolio of agriculture together with the premiership of the Transvaal, and in the Union was also for a considerable period minister of Agriculture as well as prime minister. General Botha gave full encouragement to the technical and scientific staff. Schools of agriculture—there were five in 1921—and experimental stations were established on large farms situated on main railway lines. A two years' course of instruction was provided as well as shorter courses and up to 1920 some 5,000 students had passed through the schools. Of the 300 experts in the department in 1921, over one-third were ex-students. Up to that year £1,000,000 had been spent on buildings and equipment.

The veterinary service did invaluable work in investigating the diseases of stock, discovering the causes of East Coast fever, and other diseases, some of which were eradicated. Its work rendered possible the keeping of animals in many districts where it had not previously been possible, and made profitable the importation of high-class live stock. In 1920 it was estimated that the value of the live stock in the country, chiefly cattle and sheep, was over £100,000,000.

The entomological and botanical divisions were also active, one notable achievement being the ridding—at least temporarily—of the country from locust plagues. This was done by tracking the locusts to their breeding places and as soon as the young were hatched (when they crawl, but do not fly) sprinkling them, and the surrounding veld, with a mixture of arsenic and molasses, a plan devised by a Natal farmer. This method proved so effective that in 1918–20 no swarms of locusts were reported in the Union.

New crops and plants were introduced, among them *kaff* grass from Abyssinia, very valuable for hay, which in 1920 was grown on 234,000 acres. The general result of the Agricultural Department's work, backed by the rise in prices during the World War, was to make S. Africa almost self-supporting as regards food-stuffs, while in 1919 agricultural and pastoral exports were valued at £33,000,000, and in 1920, a year of depression—especially in the ostrich feathers trade—at £27,000,000. In the back-veld farming had been "transformed from what was little more than nomadic grazing to an organized industry and throughout had been placed on a higher plane."

Of pastoral industries the breeding of woolled sheep is the oldest and most important. The number of woolled sheep in the Union was 21,842,000 in 1911, 26,400,000 in 1916 and 23,548,000 in 1919. The number of other sheep, 8,814,000 in 1911 had, however, declined to 4,943,000 in 1919. These figures did not include sheep in native locations, which in 1919 numbered about 2,250,000. The wool exported from the Union reached 176,971,000 lb. in 1913 and was 115,634,000 lb. in 1918. The World War sent up prices, the average price per lb. in 1913–4 being 7.95d. and in 1917–8 20.78d. In 1918–9 when the average price was 20.08d. the value of the wool exported was £14,648,000. Wool worth £5,678,000 went to the United Kingdom, £5,209,000 to the United States and £2,786,000 to Japan. France and Canada were the next largest customers. There is also a considerable trade in sheepskins; the value of the skins exported was £594,000 in 1911 and £1,329,000 in 1918.

South Africa produces more than half the world's supply of mohair. The Angora goats in the Union in 1918 numbered 5,278,000, mohair exported that year was 19,645,000 lb., valued at £1,641,000. The trade in mohair is subject to wide variations, and the limit of production in S. Africa is that of successful competition with Turkey for the supply of the Bradford market. In 1920 the value of mohair exported fell below £500,000, chiefly owing to lessened demand for yarn from Bradford by Poland and Germany.

The number of cattle in the Union rose from 5,796,000 in 1911 to 7,255,000 in 1919. The steady progress of the cattle industry is seen in the figures of imports and exports of meat.¹ Up to and including 1913 imports greatly exceeded exports. Thus in 1913 the quantity of meat imported was over 11,000,000 lb., and that exported but 1,387,000 lb. In 1917 the imports had fallen to 23,000 lb., while the exports had leapt to 47,250,000 lb. (valued at £1,043,000). This was an exceptional war-time condition, but in 1919 while there were no imports the exports reached 44,408,000 lb. In 1916, for the first time, sufficient butter and cheese were made in the Union for all local requirements and something left over for export. The total export of butter in 1918 was 1,316,000 lb., of cheese 424,000 lb. In 1919 butter exports fell to 452,000 lb., but that of cheese increased to 1,546,000 pounds.

Large areas of S. Africa are well adapted to horse-breeding; in general, horses do well wherever conditions are best suited for sheep. The numbers of horses in the Union in 1919 was 695,000, of mules 81,000, of asses 498,000. These figures do not include horses, etc., in native locations.

Ostrich-farming suffered severely through the World War. In 1913 the industry had attained unprecedented success, when feathers weighing 1,023,000 lb. valued at £2,953,000 (an average value of £2 17s. 9d. per lb.) were exported. In that year there were 776,000 ostriches in the Union (757,000 of them in the Cape province). Over-production and the effects of the war in five years brought about an almost total collapse of the feather trade; the export fell by three-fourths and prices to 15s. a lb. Many breeders took up other branches of farming and by 1920 few persons were wholly dependent on ostriches for their living. The stock of birds was greatly reduced (it was 314,000 in 1918), only those of finest plumage being retained.

The pig and bacon industry is a development wholly post-Union. Pedigree animals were imported but the industry had barely got beyond infancy in 1920. The total production of bacon in the Union in 1917–8 was slightly over 7,000,000 pounds.

Among cereals the most important crop is maize. The maize belt covers a large area in the eastern portion of the Union, chiefly in the Transvaal and Orange Free State. There is an expanding home market for maize and an assured overseas market. The quantity of maize exported was 356,000,000 lb. in 1910 valued at £603,000 and 500,000,000 lb. in 1918, valued at £1,600,000. Kaffir corn, grown chiefly by natives, specially valuable for fodder in

¹ Consult a paper on S.A. Agriculture by F. B. Smith, sometime secretary of the S.A. Agricultural Department, read at a meeting of the Colonial Institute, May 31 1921.

² The figures relate to beef and mutton but the quantity of mutton exported is small, 62,000 lb. in 1910 and 46,000 lb. in 1919.

regions too dry for maize, was also an increasingly valuable crop. The area under wheat is mainly in the western part of Cape province; the production, 362,000,000 lb. in 1911, rose to 608,000,000 in 1917-8, but fell the next year to 478,000,000 lb. Of oats 48,454,000 lb. were exported in 1919.

Sugar plantations are confined to Natal and Zululand. The area under sugar in 1916-7 was 163,000 ac., the production that year being 114,000 tons and the value £3,134,000. In 1919-20 the output was approximately 180,000 tons, of which over 30,000 tons were exported. The cultivation of tea declined, sugar yielding greater profits; the yield for 1916-7 was 1,747,000 lb., compared with 2,681,000 in 1903, the year of highest production. Tobacco production did not show great variation in quantity during 1910-20, the yield being 15,000,000 to 17,000,000 lb. yearly, but there was considerable alteration in the class of tobacco grown, due to the increased demand for light and medium varieties. Cigarettes from locally grown Turkish tobacco became very popular.

Fruits of many varieties are produced for which there is a very large home demand, especially in the mining areas. The export trade, in fresh, bottled, canned and dried fruit and in jams showed a fair amount of extension and in 1919 was valued at £125,000.

Plantations of black wattle for the production of tan-bark cover about 250,000 ac., of which 160,000 are in Natal. Before the World War the bark was taken by Germany; factories for the production of the extract were erected in Natal in 1919 and the extract sent to Great Britain. The value of the exports increased from £269,000 in 1916 to £412,000 in 1918.

Irrigation.—Considerable progress was made in local irrigation schemes, but no great project had been undertaken by the Union Government up to 1922. The opposition of vested interests stood in the way of an adequate water law for the whole country, but in 1912 an Irrigation and Conservation of Waters Act was passed and an Irrigation Department created. Provision was made for irrigation loans to private persons and to irrigation boards, and for hydrographic surveys, etc. The government expenditure on irrigation increased from £276,000 in 1912-3 to £573,000 in 1917-8. By 1920 schemes involving an expenditure of £2,500,000 had been approved. The Sunday river, Cape province, irrigation works were the largest then under construction and were designed to bring 42,000 ac. under cultivation.

Mining.—Despite appearances the most valuable mineral in S. Africa is coal. The position was put succinctly in 1920 by Mr. U. P. Swinburne, Chief Inspector of Mines, when he wrote in the *Official Year Book of the Union* "S. Africa has made its name through the production of gold and diamonds, but it is mainly due to the existence of cheap coal that the large output of gold and diamonds has been made possible. On the Witwatersrand proper only a few mines would be working at the present time if a plentiful supply of cheap steam coal was not available." Opinions of experts on the life of the gold mines on the Rand differ; the report of the Union Economic Commission, presented early in 1914, estimated that 550,000,000 tons of payable ore remained in the mines then working. This figure was very much less than had been expected. Since that year new mines on the Far Eastern Rand have been developed. Mr. P. A. Wagner, in his presidential address in 1918 to the S.A. Association for the Advancement of Science, hazarded the conjecture that £1,200,000,000 worth of gold remained to be extracted and that 50 years ahead some of the mines might still be profitably worked. But gold production on the Rand is so costly that a slight rise in costs has on many mines a disastrous effect.

With regard to diamonds their abundance is unquestioned, and a policy of limiting supplies to keep up prices is adopted. Even so most of the diamond mines were shut down in 1920-1, a striking example of the economic depression prevailing, S.A. being the only considerable source of the supply of diamonds in the world. Depression in prices led also in 1918 to the closing of the copper mines in Namaqualand, Cape province.

Since 1912 the gold industry has become increasingly dependent on the development of the Far East Rand. Thus in 1918 the dividends paid from the Far East Rand mines amounted to £3,344,000, compared with £1,929,000 from all other Rand mines. The value in sterling of the gold output from the Transvaal mines rose from £31,973,000 in 1910 to £39,489,000 in 1916. This was considered the high water mark.¹ The value in 1917 was £38,306,000, in 1918 £35,758,000, in 1919 £35,389,000 and in 1920 £34,652,000 (for the first half of 1921 the output was £16,671,000).

The statistics of the output of diamonds reflect the purchasing power of the public. The market is strictly controlled by the producers and the only diamond field of importance which was outside the Union—that of ex-German S.W. Africa—as a result of the World War came into line with the other S.A. mines. In 1914, shortly before the war began, a conference of representatives of the diamond industry was held in London with the object of regulating the output from each mine. Though no binding agreement was then made such an arrangement is virtually in force. The value of the

diamonds extracted in 1910 was £8,746,000, in 1913, the last full year before the war, £11,389,000. In 1915 diamond mining almost ceased, the total output that year being valued at £399,000. The mines restarted in 1916, when the value of the output was £5,728,000. In 1918 the figure was £7,114,000 and in 1919 had risen to £11,734,000, thus exceeding the record of 1913. The year 1920 began well and ended badly; the market was overstocked and purchasers few. The overstocking of the market was attributed by the De Beers Co. to the sale of diamonds by the Russians—by the Soviet Government to obtain goods and by private individuals who had lost other means of subsistence. The Rhodesian output of diamonds is very small; the De Beers Co. has the right to dispose of all diamonds found in the territory. In the Premier mine, Transvaal, the system of open working still prevailed in 1921. In Sept. 1917 a fine stone of 442 carats was found in the Dutoitspan mine, Kimberley.

A very marked development of coal mining took place between 1910 and 1921. The mines of the Cape province, which yield only poor quality coal, were nearly all abandoned as the richer deposits in Natal and the Transvaal were opened up. The output from the Cape exceeded 100,000 tons for the last time in 1909, in which year the Natal fields first yielded over 200,000 tons. The total output from the Union rose from 7,112,000 tons valued at £1,869,000 in 1910 to 10,382,000 tons valued at £3,275,000 in 1917 and was 10,266,000 tons in 1919. Besides supplying cheap fuel for the gold and diamond mines and other purposes, the coal is in great demand for bunkering ships and for export to India, E. Africa and S.A. ports. In 1919 Union coal bunkered was 1,427,000 tons; coal exported 1,002,000 tons (half of these exports going via Delagoa Bay).

The output of tin, mined almost entirely in the Waterberg and Ollifants river districts, Transvaal (3,672 tons in 1913 valued at £436,000), had dropped in 1918 to 1,900 tons valued at £277,000.

Copper output increased with the opening of the railway in 1913 to the Messina mines on the Limpopo. These with the Namaqualand mines represented the copper output of the Union, which in 1916 with 22,800 tons reached a value of £1,137,000. In 1919 the output sunk to 4,900 tons valued at £208,000.

Trade and Shipping.—The following table gives the total of imports and exports to and from the Union for 1911, the first complete year after the Union had been established, for 1915, the year of the greatest restrictions of trade owing to war conditions, and for 1919. The exports include diamonds and gold, the imports government stores and specie:—

Year	Imports	Exports	Total Trade
1911	£38,035,000	£57,308,000	£95,343,000
1915	£33,833,000	£35,012,000	£68,845,000
1919	£50,791,000	£104,561,000	£155,352,000

Trade in 1920 was conditioned by the world depression, which did not become marked till the second half of the year. Imports in the first six months showed a large increase, being £48,000,000 against £28,000,000 in the corresponding period of 1919, and for the whole year exceeded £90,000,000. Exports for the first six months of 1920 showed a comparatively small decline, being £51,000,000 as against £58,000,000 for Jan.-June 1919, but for the whole of 1920 the total was only £72,000,000.

The distribution of trade by countries was as follows in 1910 and 1919:—Imports (1910) United Kingdom 59%, (1919) 46%; other British lands (1910) 11%, (1919) 17%; United States (1910) 8%, (1919) 24%; other countries (1910) 22%, (1919) 13%. Exports (excluding gold) United Kingdom (1910) 80%, (1919) 61%; other British lands (1910) 1%, (1919) 8%; United States (1910) 17%, (1919) 24%; other countries (1910) 17%, (1919) 15%.

Nearly all the external trade of the Union passed through Durban, Cape Town, Port Elizabeth and East London. The only non-British port which had a share in the trade of the Union was Delagoa Bay. In 1913 Delagoa Bay had 12% of the trade, in 1918 only 8% (see DELAGOA BAY). Of neighbouring countries the chief trade was with Rhodesia, Portuguese E. Africa and the Belgian Congo. The exports to British E. Africa (Kenya Colony) increased from £19,000 in 1913 to £396,000 in 1918; in the same period the imports from British E. Africa rose from £16,000 to £139,000. Of foreign countries outside Africa and excluding the British Empire and the United States, France and the Argentine were the chief traders with the Union. As to overseas carrying trade the British proportion of cargo shipped in 1918 was 79.85% and the Japanese 7.51. Of cargo landed the British proportion was 69.17% the Japanese 10.12% and the American 9.43%.

The value of the preferential treatment accorded certain articles of merchandise imported into the Union from the United Kingdom, Canada, Australia and New Zealand is shown by the following figures:—In 1913 on imports valued at £22,498,000 the amount rebated was £628,000; in 1918 on merchandise worth £25,158,000 the rebate was £698,000.

The number and tonnage of vessels entered at Union ports (including the coastwise trade) was as follows in the years named. The figures represent the gross number of vessels using the Union ports, i.e. the same vessel, if it called and cleared at Cape Town, Port Elizabeth and Durban, would be entered three times. The tonnage

¹ The total value of gold mined in British S. Africa in 1916 was £43,416,047: of this total £3,859,111 came from Rhodesian mines, £31,726 from the Tati goldfields, £1,336 from Natal and £132 from Cape province. The Natal mines in 1915 had yielded over £10,000.

of vessels cleared is not given, it corresponds closely to the figures of tonnage entered.

Year	No. of vessels entered	Net tonnage British	Net tonnage Total
1913	4,349	10,586,000	12,939,000
1915	3,322	7,298,000	7,937,000
1917	3,888	7,682,000	9,252,000
1919	3,060	6,612,000	7,608,000

The number of German ships entering Union ports in 1913 was 230, of 723,000 net tonnage.

Communications.—Nearly all the railways in the Union are state owned. Railways and harbours are under the control of a Board, whose finances are independent of the other revenue departments. The mileage of railways open in 1910 was 7,586, of which privately owned lines had a mileage of 545. In 1919 the mileage open was 10,049, of which government lines had 9,542 mileage. It will be seen that development was rather slow, an average of 246 m. a year in a period of 10 years. The total expenditure on new lines in these 10 years was £9,113,000. The principal new line, that from Prieska to Kalkfontein connecting the Cape and S.W. Protectorate systems, was built for military purposes. The extension in 1913 of the railway from Krugersdorp via Zeerust to Mafeking brought Johannesburg and Bulawayo within 680 m. of one another (instead of 975 m. via Fourteen Streams) and made Mafeking the business centre for the western Transvaal. The opening, also in 1903, of the Messina railway, afforded the opportunity, by the building of a connecting line to W. Nicholson in S. Rhodesia of putting Bulawayo in direct communication with Delagoa Bay. But, up to 1921, the needed link had not been built (*see RHODESIA*). In the Cape province the completion of the Mossel-Bay-George-Oudtshoorn line gave a much more direct connexion between Cape Town and Port Elizabeth reducing the distance from 910 m. (via de Aar) to 684 m. (the distance by sea between the two ports is 436 nautical miles). The adoption of electricity on a number of lines, including the main line from Durban to Glencoe was recommended in 1920 by the government's consulting engineer. The scheme was adopted by the ministry for the Cape Town-Simon's Bay line and for the Natal main line from Durban as far as Maritzburg. With the electrification of the Durban-Maritzburg line a new alignment was undertaken as part of a scheme for rebuilding the whole line from Durban to the Rand.

The Railways and Harbour Board after the World War took over control of the railways in the S.W. Protectorate. The total railway mileage in the Union and Protectorate at the beginning of 1920 was 11,334. Up to March 31 1920 the capital expenditure on Government railways was £96,408,000. The gross earnings in 1919-20 were £19,169,000 and working expenses 78.9% of the gross earnings.

The use of motor vehicles greatly increased from 1913 onwards (when over 4,000 cars were imported), farmers having by then learned their value. In 1919 over 16,000 vehicles were licensed. Nearly all the cars came from America (United States and Canada), but heavy motor lorries were imported from England. Notwithstanding this development of motor traction the trek ox was still employed though in decreased numbers.

The extension of the telegraph system kept fair pace with the needs of the community, and wireless stations were erected at Durban, Cape Town and (in 1921) at Port Elizabeth. These were not of high power, the guaranteed range (at night only) not exceeding 1,500 miles. Wireless telephonic stations were added in 1921.

With respect to the mail service to England no improvement in speed was made. A contract to run for 10 years from Oct. 1 1912 was entered into with the Union Castle Co. for a weekly service to and from Southampton, the duration of the voyage to be 16 days 15 hours. The subsidy paid was £171,000 yearly, of which £21,000 was in consideration of the mail steamers beginning and ending their voyages at Durban instead of Cape Town. The contracting parties were on the one hand the steamship company and on the other hand Great Britain, the Union, Southern Rhodesia and the Bechuanaland Protectorate. Postal communication with Australia, India and the Far East was maintained by private ships as opportunity offered. A steamship service between Holland and S. Africa, subsidized by the Netherlands Government, was established in 1920, and in 1921 a direct service between S. Africa and Vancouver was started by the Canadian Government. While some £10,000,000 or more a year was spent on harbour works except at Durban (*see DURBAN*) the facilities for shipping were not greatly extended, and Cape Town suffered from lack of adequate dock accommodation.

Air travel developed slowly. The first aeroplane flight was made in 1910 in a Voisin biplane. Little progress was made in civil aviation until after the World War, when, in 1919, aerodromes were laid out at Wynberg, Bloemfontein, Johannesburg and other places as stages on the cross-Africa route. The first flight from Cairo to Cape Town was made in 1920 by two S.A. military pilots. In the same year an Aero Club for S.A. was formed at Cape Town.

Education.—"Education, other than higher education," which definition in practice was held to include all education other than university, is controlled by the provincial councils. The standards and methods differ in each of the four provinces but in general provision is made for a sound training of white and coloured

distinct from native) children. A matter which aroused acute dimensions before and in the two years immediately following the establishment of the Union was the question of the medium of instruction. By law the English and Dutch languages were in a position of equality. An attempt to favour Dutch was made in the Transvaal schools, while in the Free State the education authorities tried to enforce bi-lingualism, insisting that English-speaking children should be taught in the medium of Dutch. Eventually all four provinces adopted the principle recommended by the Union Parliament in 1911, namely that the medium of instruction up to standard IV should be in the "home" language of the scholar, and that above that standard freedom of choice should be left to the parents. The compromise worked and in June 1912 the private schools which had been opened by the English speaking residents in the Free State in 1910 as a protest against compulsory bi-lingualism were handed over to the provincial administration. The subject of religious instruction presented little difficulty. The practice in each province in all public schools is for school to be opened with prayer and a reading from the Bible. Scripture teaching, subject to a conscience clause, is generally provided; sectarian teaching under certain conditions is allowed in the Cape province by an ordinance passed in 1913. The number of schools in the Union for white children increased from 3,873 in 1910 to 4,846 in 1918; in the same period the schools for coloured children increased from 1,999 to 2,877. The number of white scholars in 1910 was 163,200, in 1918 the number was 283,100. The coloured scholars had increased in the same period from 136,000 to 220,100. The teachers had increased from 10,912 to 18,301, and the expenditure from government funds had grown from £1,597,000 to £3,631,000. Private schools were not numerous; there were 270 in the Union in 1918, of which 96, the oldest dating from 1880, were in the Cape province. There were then in the Union 135 private schools founded since 1910.

State and state-aided schools for natives are provided in all the provinces, and in Natal and the Transvaal there are special schools for Indians. The expenditure on native schools rose from £81,000 in 1911 to £137,000 in 1918. In Natal in 1918 the government established an institution for training the sons of chiefs and *indunas* in the special duties they are called upon to perform. The education of the natives remained, however, very largely in the hands of missionary societies, though there was a growing inclination, among the natives, particularly in the Transkeian territories, to secularize education and to obtain a larger direct share in its management. Of the 23 principal institutions which in 1919 provided higher education for natives—literary, commercial, industrial, agricultural and training for the ministry—12 were in Cape province, the largest and most comprehensive being the famous Lovedale College. The most important step in regard to higher education of natives was the establishment in 1914 of the S.A. Native College on a site at Fort Hare, Cape province, given by the United Free Church of Scotland. To this college the natives and the missionary societies, Presbyterian, Anglican and Wesleyan, contributed, the Union Government gives an annual grant. The college aims at providing education of university standard and is open to coloured and Indian students.

The system of higher education was reorganized in 1918, after much heated controversy (*see below § History*). Under the new scheme the university of S. Africa, with headquarters at Pretoria which replaced the university of the Cape of Good Hope, is an examining body, having the following constituent colleges:—Grey University College, Bloemfontein, Huguenot College (for women) Wellington, Natal University College, Pietermaritzburg, Rhodes University College, Grahamstown, South African School of Mines Johannesburg, and Transvaal University College, Pretoria. The new university of Cape Town provides for the residence as well as the teaching of students (men and women). A special feature of the new Stellenbosch University is its agricultural faculty (the Transvaal University College has also an agricultural faculty). The number of university students in the Union increased from 1,171 in 1910 to 2,069 in 1918. In the last-named year the expenditure on higher education in the Union was £240,000.

Finance.—The unitary system of government adopted in 1910 was strongly marked in the financial provisions made. All public revenues were payable to the Union Government, and the fund needed to carry on the administration of the provinces were provided by grants from the Union Exchequer. By the Financial Relations Act which came into force in April 1913 the Union Parliament assigned the revenue derived from transfer duties, liquor licenses and native pass fees in Transvaal labour districts to the provinces, but gave the provinces no power of legislation in regard to such revenue. Other sources of revenue, such as education fees, trading and professional licenses were assigned to the provinces with power of legislation in regard thereto. A subsidy from Union funds of one half the ordinary expenditure of the provinces was also made, plus additional subsidies to Natal and the Orange Free State whose funds were shown to be inadequate to meet the necessary expenditure. The provinces are not allowed to borrow from any other source than the Union Treasury.

All trust moneys, (e.g. post office savings bank moneys) are handed over for investment to the Public Debt Commissioners. Any year's surplus of revenue over ordinary expenditure is paid to the Commissioners and by them applied to the redemption of debt.

Revenue and expenditure of the Union is divided into two distinct funds, the ordinary or general, and the railway and harbours.

The following table shows the ordinary revenue and expenditure, for three typical financial years —

	1913-4	1916-7	1920-1
Revenue	£15,980,000	£18,617,000	£28,381,000
Expenditure	£14,289,000	£15,490,000	£28,890,000

The chief sources of revenue for the year 1919-20, were as follows: customs, £5,010,000; interest, £1,277,000; income, super, and dividend taxes, £4,050,000; posts, telegraphs and telephones, £2,031,000; excise, £1,228,000; and mining revenue, £1,023,000. The native poll and hut taxes produced altogether, £830,000. Among the main items of expenditure for the same period were: public debt, £6,940,000; provincial administrations, £3,520,000; justice, £3,200,000; postal, etc., services, £2,144,000; defence, £1,575,000; pensions, £1,200,000; interior, £1,019,000; agriculture, £861,000; and public works, £614,000.

Railway and harbour finance is controlled by a board presided over by a cabinet minister. The management of harbours and railways is required to be upon business principles. The following table shows receipts and expenditure for these services in the 3 years named —

	1913	1916	1918-9
Harbours (receipts)	£1,039,000	£1,031,000	£1,039,000
" (expenditure)	£900,000	£856,000	£470,866
Railways (receipts)	£12,388,000	£13,257,000	£11,680,000
" (expenditure)	£8,964,000	£8,891,000	£15,282,000

The war expenditure of the Union was met out of loan funds, the total charge on such funds amounting on March 31 1920 to £29,736,000. At the same date the public debt of the Union was £173,905,000.

THE SOUTH-WEST PROTECTORATE

After the surrender, in July 1915, of the German forces in S.W. Africa Gen. P. S. Beves was appointed military governor of the protectorate.¹ None of the German inhabitants was then repatriated and while the regular troops were placed in internment camps the civilians were allowed to return to their homes and continue their ordinary business. Mr (afterwards Sir) E. H. L. Gorges, Secretary of the Interior in the Union, who had at Gen. Botha's request already drawn up a scheme for the future administration of the protectorate was made chief civil secretary. On Oct. 30 1915, on Gen. Beves's departure the two offices named were abolished and the functions of both taken over by Mr. Gorges with the title of Administrator. This post he retained until nearly the close of the military occupation period, which lasted till the end of 1920. Martial law remained in force but in a mild form and the administration was on civilian lines. At the beginning of 1917 it was found necessary to send an expedition to Ovamboland, the northern and most populous part of the protectorate, where German authority had been very slight. A chief named Mandume proved recalcitrant and two battalions, the first and the fourth of the S.A. Mounted Riflemen, together with a composite regiment of military constabulary were sent against him, Col de Jager being in command. The expedition, despite fever, flood and dense forest, as well as the opposition of the natives, was successful. Excellent relations were afterwards established with the Ovambo.

In the rest of the protectorate S.A. rule was from the first welcomed by the natives, and the Germans gave no serious trouble. Until nearly the close of the World War they believed that the British occupation was temporary, being confident in the ultimate victory of Germany. This was evidenced by the fact that the German banks and traders maintained a rate of exchange of 24 marks to the £ sterling until Nov. 1918—the month of the Armistice. Instances were known of farmers selling their stock for nothing and converting it into paper marks. Where the artificial rate of exchange broke down serious losses followed. The German Government, however, continued to entertain false hopes, and after the war they wrote to President Wilson asking his help in "re-establishing" lines. They desired, they said, to become an autonomous republic leagued to the German republic, and in addition, they gratuitously added, would, they believed, carry out the wishes of the natives. In 1919 the German

¹ For earlier years see GERMAN SOUTH-WEST AFRICA.

soldiers—about 5,800 in all—together with some 600 "undesirables" were repatriated. This still left, according to official figures, over 9,000 Germans in the protectorate. These German settlers continued hostile to Union rule, and obnoxious to authority. Lord Buxton, then governor-general of the Union, who visited Windhuk, the capital, in Oct. 1919, took occasion to inform them that the severance from Germany was irrevocable, and that the protectorate would in future form an integral part of the Union. Gen. Smuts when on an official visit to the territory in Sept. 1920 used similar language. The Germans had informed him that the country should be administered as "an independent province," and that the German civil code should continue, arguing that the introduction of the Roman-Dutch law would be "a retrogression of centuries." They also asked for the recognition of German as an official language, and the maintenance by the State of the German schools, but were refused.

By the treaty of Versailles Germany had renounced sovereignty over the protectorate, and in accordance with its provisions the Supreme Council in May 1919 assigned the mandate for the territory to the Union of S. Africa. An Act was passed by the Union Parliament in Sept. 1919 to give effect to the mandatory powers, finally the mandate was confirmed by the Council of the League of Nations on Dec. 17 1920. On Jan. 3 1921, martial law was withdrawn and Mr. Gysbert Hofmeyer, who had succeeded Sir Howard Gorges as Administrator in Oct. 1920, was given a nominated advisory council of six members. This council met for the first time on Feb. 2 1921.

Settlers and Industries—In general the laws in force in, and the economic policy of, the Union was applied to the protectorate from the early days of Sir Howard Gorges's rule. Walvisch Bay, the only good harbour on the S.W. coast, had languished. It had formed a small British enclave in what was German territory, and without hinterland, served only the purpose from which it got its name—a whaling station. Swakopmund was an artificial and poor port. The Union authorities built a line (22 m. long) from Walvisch Bay to Swakopmund, and thus gave the protectorate its natural sea outlet. The whole length of the line from Walvisch Bay to Windhuk was ruled on the standard S.A. gauge of 3 ft. 6 inches. In 1921 the Railways and Harbour Board undertook the construction of a line (132 m. long) eastward from Windhuk to Gobabis.

While no crown lands were alienated up to 1921 temporary licences were granted and many members of the army of occupation on demobilization settled in the country with their families. A fairly large British-Dutch population soon grew up, evidenced sufficiently by the fact that in 1920 there were 975 children attending Government schools. The new settlers were chiefly engaged in stock raising and farming, the copper, tin, and diamond mines were already in beneficial occupation, largely with British capital. The Otavi mines in the years 1916-8 produced 100,000 tons of copper ore, valued at £600,000. The expectation that the Lüderitzbucht (Luderitz Bay) diamond fields would be thrown open to all comers was not realized. At the end of 1915 some of the companies on the diamond field were allowed to resume work; between Oct. 1915 and Jan. 1919 diamonds valued at £1,900,000 were obtained. Later the whole diamond field came under the control of one company, which entered into a working arrangement with De Beers and other diamond mining companies in the Union. The depression in trade led, in 1921, to the temporary closing of the mines. Depending upon diamonds for prosperity, was, declared Mr. Hofmeyer, like building on sand.

Trade and Revenue—During the war external trade was all overland with the Union, trade being facilitated by the line built in 1913 from Prieska to Kalkfontein to connect the two railway systems. Customs duties were those in force in the Union, with free trade between the Union and the protectorate. During 1918 the value of imports was £1,031,000, about one half being S.A. produce. Of the total imports £409,000 represented the value of food and drink, and £181,000 cotton goods. The value of exports in 1918 was £817,000. The chief items were, diamonds £652,000, copper ore £55,000, cattle and small stock £57,000, horns, hides and skins £35,000.

The revenue of the protectorate in the financial year 1917-8 was £295,000; and in 1918-9 £377,000, of which £275,000 was from the tax on diamonds. The expenditure for the two years named was £650,000 and £744,000; as to more than three-fourths the expenditure was on the upkeep of the garrison.

Native Affairs—Nowhere else had German methods of dealing with the natives been more ruthless than in S.W. Africa. The result of an examination of German judicial and administrative methods and documents was made public in 1918. It showed that not only

¹ The German settlers had separate schools. Efforts were made in 1921 to induce them to abandon these schools. They were offered "mother-tongue" instruction up to standard VI., coupled with the compulsory learning of either English or Dutch.

during the Herero and Hottentot wars but in peace time the natives were systematically subjected to brutalities and robberies, by the Government as well as by the settler. One consequence was that, apart from Ovamboland, where the Germans had little authority, the native population had decreased from some 130,000 in 1904 to 37,000 in 1911. In 1920 it was estimated at 80,000. To reconstruct, as far as practicable, tribal organization, Sir Howard Gorges established native reserves (over 4,000,000 ac. in all) controlled by hereditary chiefs, when such survived, or by an elected or nominated headman. To these men small salaries were given. Rules to protect natives in the railway and other public departments and in European private service were enforced.

THE NATIVE PROTECTORATES

No change was made in the political status of the native protectorates—Basutoland, the Bechuanaland protectorate and Swaziland—in the period 1910-21. They remained under the control of the Colonial Office, represented by the High Commissioner for S.A. and were administered by resident commissioners. They form in whole, or in greater part, native reserves, and the Basuto and Bechuana showed marked disinclination to incorporation in the Union of S. Africa. All three protectorates prospered.

Basutoland.—At the 1921 census the people numbered 500,544 (of whom 1,615 were whites and 155 Asiatics) compared with 403,845 in 1911 and 348,848 in 1904; of the total pop. in 1921 males numbered 224,435 and females 276,109. Maseru, the capital and largest town had (1920) approximately 900 native and 500 white inhabitants. Outside Maseru, the white residents are nearly all officials or missionaries. Ownership of land by whites is forbidden. Some 20,000 male Basutos are normally employed outside the country—mostly on the Rand gold mines. Agriculture and stock raising are the chief occupation of the people.

Education is in the hands of the missionary societies, except for four small Government schools. In 1919 there were in all 344 schools with 28,500 scholars, most of the schools being maintained by the French Protestant Mission (the Paris Evangelical Society). Grants in aid are made by the administration (£25,000 in 1920-1). Serious crime is rare and the drinking habits of the people, which once threatened their destruction, have been very largely abandoned under missionary influence. About one-fourth of the Basutos prefer Christianity. Trade is almost exclusively with the Cape and Free State provinces; the Basuto export grain, cattle, wool and mohair, and horses, and import mainly clothing, ploughs, saddlery, iron and tin ware, and groceries. The value of imports increased from £239,000 in 1908 to £1,137,000 in 1919. In the same period the value of exports rose from £193,000 to £1,380,000—in part due to inflated prices obtained for wool and mohair.

Financially Basutoland is self-supporting. Revenue is obtained from customs, licenses and, principally, from the poll tax on natives. This tax was substituted in 1911 for the hut tax previously enforced. A tax of £1 per annum on adult males was then put in force, but if a Basuto had more than one wife, he paid £1 per annum for each wife, up to a maximum of £3 for himself and his wives. This tax yielded £92,000 in 1913 and £106,000 in 1918-9. Total revenue increased from £145,000 in 1910-1 to £199,000 in 1919-20, the corresponding figures for expenditure were £134,000 and £202,000.

The system of government which under a resident commissioner allows a measure of home rule to the Basutos continued to work well. The *piso* or national council meets yearly, 95 out of its 100 members being nominated by the chiefs and the other five by the administration. It has advisory powers only, but its advice is often taken. Sir H. C. Stoley who had been resident commissioner since 1901, and who earned the full confidence of the people, was in Dec. 1917 succeeded by Lt.-Col. E. C. F. Garraway. Letsie II., who had been paramount chief since 1905, died in Jan. 1913. He was a great grandson of Moshesh, the founder of the Basuto nation and dynasty, and was succeeded by his brother Griffith. When the World War began Griffith and his people offered to raise regiments for combatant service. The offer was declined, to the grief of the Basutos, to whom service with the labour contingent did not appeal. However, 1,400 Basutos served with the S.A. Native Labour Contingent in France, and many were employed in S.W. and E. Africa. The Basuto also contributed £50,000 to war funds. In 1921 the new High Commissioner, Prince Arthur of Connaught, visited Maseru, and the presence of a member of the royal house was made the occasion for a national tribute by the "Sons of Moshesh"—as the Basutos call themselves—to their loyalty to the British throne and their wish to remain directly under imperial control.

Bechuanaland.—The Bechuanaland protectorate is a much poorer country than Basutoland and the Bechuana are a less virile race than the Basuto. Bathoen, paramount chief of the Bangwaketse, died in July 1910 and Sebele, paramount chief of the Bakwena, died in Jan. 1911. Montsioa, chief of the Baralong, died in April 1911. All these chiefs were noted men in the early struggles between the Boers and British for the possession of Bechuanaland, Sebele being a son of the chief Sechele, the friend of David Livingstone. Khama,

the chief of the Bamangwato, and a Christian from his youth, still survived in 1921 and had then ruled over his people with undisputed authority for some 50 years.

The Bamangwato are the largest tribe, numbering about 40,000. The people grow maize, kaffir corn and other crops but their chief wealth is in cattle, and cattle hides and skins are the chief exports. Firewood and timber for mining props are also exported. In 1917-8 exports to the Union included 23,600 horned cattle and 36,000 sheep and goats. The chief markets are Kimberley, Mafeking and Johannesburg. For customs purposes the protectorate is dealt with as part of the Union and no statistics as to value of imports and exports are kept. Revenue, £52,000 in 1910-1, first exceeded expenditure in 1915-6, when the figures were revenue £70,000, expenditure £68,000. In 1919-20 revenue was £81,500, expenditure £91,600. Deficits were made good by grants from the Imperial Exchequer. The seat of the administration is Mafeking, in the Cape province. Mr. J. C. Macgregor became resident commissioner in 1917. Khama's headquarters are at Serowe (pop., 1920, about 25,000).

Swaziland.—At the 1921 census the inhabitants numbered 113,772, of whom 2,203 were whites. Of the total pop. 54,702 were males and 59,070 females. The state of chaos into which Swaziland had fallen owing to the indiscriminate grant of concessions (see 26 181) was ended by 1914. The partition of rights between the European concessionaires and the Swazis was completed in 1911, and those natives who were required to move from properties held by whites by July 1914, did so voluntarily—such as did move, for many natives made terms with the concessionaires and remained on their farms. Out of a total area of 4,274,000 ac. 1,635,000 ac. were set aside as Swazi reserves, in addition the Swazis bought 77,000 acres. The Swazis raise maize and other crops and own large stocks of cattle while 7,000 to 10,000 Swazis are usually at work on the Rand mines. The whites engage in agriculture, including fruit farming and cotton and tobacco growing and in mining. The gold mines, which produced 6,497 oz. in 1915-6, were closed down as unprofitable in 1917. Tin of a total value of £346,000 was produced in the years 1915-20. The large coal deposits in the protectorate had not been exploited up to 1921. No separate statistics of Swaziland trade are kept. Revenue which in 1910-1 was £58,000 had risen to £91,800 in 1919-20. Expenditure in the same period rose from £62,000 to £87,000. The settlement of the concessions' questions cost £182,000.

The administration is under the charge of a resident commissioner, with headquarters at Mbabane, a small, picturesquely situated hill village (altitude 4,000 ft.) overlooking the middle veld. The paramount chief and other chiefs exercise jurisdiction in all civil cases in which natives only are concerned. Naba Tsbenti, the "queen regent," a well-known figure in Swazi history acted for many years as paramount chief, until the coming of age of her grandson Sobhuza (born about 1900). Education is mainly in the hands of missionaries; Sobhuza was educated at a Government school established at Naba Tsbentis Kraal. Mr. De S. M. G. Honey who had served in Swaziland since 1904 became in 1917 resident commissioner.

HISTORY

The 12 years (1910-21) following the establishment of the Union of S.A. were marked by political, racial and industrial crises which profoundly affected the future of the country. The most urgent issue was raised by a powerful section of the Dutch community, which revived a narrow Nationalism and developed a demand for the separation of the Union from the British Empire. Coupled with this conception went strong opposition to action against Germany, or any share in the World War. But this Nationalist section, whose greatest figure was ex-President Steyn and whose mouthpiece was Gen. Hertzog, was unable to control events. The policy of Gens. Botha and Smuts of "building up a new State on non-racial lines" and as an equal member of the British Commonwealth prevailed.

Besides this main issue the growth of an organized Labour party, which found its chief stronghold on the Rand and put forward an advanced socialistic programme, presented perplexing problems to a community new to such manifestations. The position of Indians in the Union, and the resolve of the white races to prevent further immigration of Asiatics was another problem which caused acute controversy, only partially allayed by the ultimate assent of the Government of India to the policy of exclusion. And behind all these questions, the old and new present problem of the relation between the white and native races. Signs multiplied that the Bantu population was increasing in knowledge and an increasing factor in industry, and acquired a sense of race solidarity and would not rest satisfied with their existing economic, social and political status.

While these racial and political questions were being dealt they were accompanied by a steady development of the material

resources of the country and of trade. The progress in agriculture and in mining was marked, a beginning was made in manufactures. The benefit of unification in this respect was apparent. That benefit was even more apparent in the relations of S.A. with the outside world, she spoke with one voice and as a powerful unit. The new position which S.A. had acquired, in common with the other British Dominions, was seen when as a separate entity she was represented at the Peace Conference in Paris and her delegates signed the Treaty of Versailles.

Outside the Union the period under review was chiefly noticeable for two things: the disappearance of German sovereignty accompanied by the transfer of the administration of ex-German S.W. Africa to the Union, and the decision to terminate the government of Rhodesia by the Chartered Company, in response to the demand of Rhodesians for self-government.

The Union had been brought about by the recognition by the leaders of the Dutch and British communities that S.A.

was one country, not several, and that in every part of it the interests of the two races were so intermixed that they could not be separated without harm to both. Lord Gladstone, the first governor-general of the Union, had called upon Gen. Botha, the Prime Minister of the Transvaal, to form the first Ministry under the Union.¹ This Gen. Botha had done and this Ministry came into existence on May 31 1910, the day on which the Union was proclaimed (being the eighth anniversary of the close of the Anglo-Boer War). General Botha's Ministry was formed from members of the expiring Cabinets of the various colonies, but while it included Natal ministers and strong Boer partisans it was not a coalition ministry. The first general election, held on Sept. 15 1910, was fought on party lines and was hotly contested. It resulted in a majority for the "South African" party, that led by Gen. Botha, of 13 over all other parties, though Gen. Botha himself was defeated at Pretoria East by Sir Percy Fitzpatrick and a seat had to be found for him by means of a by-election. In the first session of the Union Parliament (opened by the Duke of Connaught on Nov. 4) Gen. Botha had the support not only of his own party, but of that of the four Labour members elected by Rand constituencies and of several of the Natal members of whom 13 out of 17 had been returned as Independents. The opposition, known as the Unionist party (and mainly British) was led by Dr. Jameson, who was created a baronet in Jan. 1911. Owing to ill health Jameson resigned the leadership in April 1912, and was succeeded by Sir Thomas Smartt, an ex-Cape minister and, like Jameson, a medical man. In Oct. 1912 Jameson resigned his seat for Albany (Graham's Town) and retired from Parliament.

General Botha's Cabinet was of a rather heterogeneous character. Among its members were Gen. Smuts, Mr. H. C. Hull, Mr. Jacobus Wilhelmus Sauer, Mr. Henry Burton, Mr. Abraham Fischer and Gen. Hertzog. They were divided on personal and provincial as well as progressive and retrogressive lines. General Smuts, Minister of the Interior, did not at first figure very prominently, but was the Prime Minister's right-hand man. Mr. Hull (b. 1860), after being in the Cape civil service, had practised at the bar, served in the war of 1899-1902 and was afterwards Treasurer of the Transvaal, and he entered the Union Cabinet as Minister of Finance. Mr. Sauer had been 30 years a member of the Cape House of Assembly and had frequently held office. In Gen. Botha's Cabinet he was Minister of Railways and Harbours and chairman of the Railways and Harbours

Board, and thus head of the largest revenue producing department of State. Mr. Fischer and Gen. Hertzog represented the extreme element among the Boers. They were both from the Orange Free State, of which (as the Orange River Colony) Mr. Fischer had been Prime Minister. In the Union Cabinet he became Minister of Lands and Gen. Hertzog Minister of Justice.

The first session of Parliament was devoted mainly to putting the Union machinery into working order. It was not until towards the close of 1912 that Gen. Hertzog publicly abandoned the principles on which the Union had been established, though there was no doubt of his belief that the Dutch community had a prescriptive right to dominance in S. Africa. The most controversial issue considered in the 1911-2 session arose out of the Education Acts of the former Orange River Colony (see 20.160), where, during its brief period of self-government, Gen. Hertzog as Minister of Education had enforced bi-lingualism in the state schools. By the Act establishing the Union education "other than higher education" had been left in the control of the provincial councils for a period of five years, after which Parliament was free to take what action it pleased. In the meantime it could only advise. A select committee on which the S.A. and Unionist parties were equally represented considered the subject and on April 17 presented a majority report recommending that instruction up to Standard IV. should be given in and through the "home language," with the optional use, on the demand of parents, of the other language, and that above Standard IV. freedom of choice in the medium of instruction should be left to the parents; also that teachers should be free to qualify in either language (English or Dutch). This was a reversal of Gen. Hertzog's policy, but though he disliked this compromise it was accepted by the Union Parliament (April 24). During 1911-2 the provincial councils of the Transvaal, Free State and the Cape passed ordinances adopting the compromise, though with some modifications in favour of Dutch. This virtually ended the language controversy as far as schools were concerned, and the provincial councils taking a liberal view of their duties, their control over elementary and secondary education was continued even after the lapse of the five years provided in the Union Act. But Gen. Hertzog's position was much shaken during the controversy over the medium of instruction. The success of an action for slander (Aug. 1911) brought against him by Mr. Wm. Fraser—Free State inspector of schools whom Hertzog had dismissed in 1900—caused much scandal, which was intensified by the success (Nov. 1911) of another slander action brought against him, the second plaintiff being Dr. Ward, president of the O.F.S. medical council. The situation was rendered piquant by the fact that Hertzog was Minister of Justice. He tendered his resignation, but Gen. Botha, not wishing to alienate the Boer extremists, refused to accept it.

Having brought about a settlement of the language question in elementary schools the Union Parliament was called upon to deal with higher education. The only university in S.A. at the time of the Union was that of the Cape of Good Hope, founded in 1873, with its seat at Cape Town. It was an examining body, with affiliated colleges. Demands for teaching universities had grown up and the Union Government had to deal with an offer of £500,000, half of this sum being a bequest by Sir Julius Wernher, the other half being given by Messrs. Alfred and Otto Beit. This money it was desired should go to establish a national university on the Groote Schuur estate, near Cape Town. A bill to give effect to this proposal was introduced into Parliament in the session of 1913. It met with much criticism and was withdrawn, a strong University Commission being appointed in Nov. 1913 to enquire into the subject. Its report, issued in 1914, is a valuable document, dealing fully with the lines of possible development, though the Commission was fain to acknowledge that the many vested interests constituted an "almost insoluble" problem. It recommended two universities—one at Cape Town and one at Pretoria, to one or other of which the existing university colleges would be attached. This recommendation provoked almost as much criticism as had the bill of 1913.

¹ Mr. J. X. Merriman, as Prime Minister of the Cape, the oldest colony in S.A., had some claim to be called upon to form the first Union Ministry, but his claims were passed over. He declined to serve under Gen. Botha. It appears, however, from the biographies of Jan Hofmeyr and of ex-President Steyn that both Botha and Merriman were prepared to serve under Steyn. Steyn was an invalid, and his doctors forbade him to entertain the idea of taking office. The ex-President was against a coalition Ministry, among other reasons because he feared that had Dr. Jameson been in the Cabinet he would have pressed for the inclusion of Rhodesia in the Union. While Steyn had favoured the Union movement he was not prepared even in 1910 to accept its full consequences. See J. H. Hofmeyr, *Onze Jan.* (1913) and Van der Merwe's "Life" of Steyn (in Dutch 1921).

The Dutch community strongly opposed the proposal that Victoria College, Stellenbosch, founded in 1866 as the Stellenbosch Gymnasium and mainly attended by Dutch students, should be incorporated in the Cape university. A solution of the difficulty was reached in 1916 when Parliament passed Acts establishing three universities: the university of South Africa, the university of Cape Town, and the university of Stellenbosch. The two last were to be teaching universities and the seat of the Cape Town University was to be at Groote Schuur. It was formed by incorporating the South African College (founded at Cape Town in 1829) and to it the £500,000 of the Wernher-Beit bequests accrued.

The university of South Africa took the place of and was the legal successor of the university of the Cape of Good Hope, headquarters being removed from Cape Town to Pretoria. The new university, like its predecessor, was a federal organization with examining functions. Its first chancellor was the Duke of Connaught. The changes became effective on April 2 1918.

In the 1911-2 session of Parliament an attempt was made to grapple with the relations of the white and Kaffir races, the position of Asiatics in the Union and with national and imperial defence. General Botha with two of his colleagues (Sir David de Villiers Graaff and Mr. F. S. Malan) had attended the Imperial Conference held in London in May and June 1911, when the Asiatic question and defence had been considered. The Union Government decided that S.A. should provide for its own internal defence, and a Defence Act was passed in June 1912, creating a citizen force at a cost of about £500,000 a year, this is in addition to a permanent force of five regiments. The Act provided for the military training of 50% of the young men between 18 and 21; the other 50% being compelled to join rifle clubs and similar associations. The 50% for training are obtained in the first place by voluntary enlistment, but if sufficient numbers are not forthcoming by this method, then by ballot. (Recourse to the ballot had not been necessary up to 1922.) Members of the Citizen Force with the colours are paid. Provision was made for artillery, cavalry, infantry, engineer and transport units, uniformity with the units of the other overseas dominions being aimed at. General C. F. Beyers, one of the Transvaal commandants in the Anglo-Boer War, was appointed commandant-general, while the Council of Defence created by the Act consisted of Gen. Schalk Burger (Transvaal), Col. (afterwards Sir) Charles Crewe (Cape), Gen. de Wet (Orange Free State), and Col. Sir Duncan Mackenzie (Natal).

Objections to the Act came chiefly from the "back-veld" Boers who entertained strong dislike to compulsory service. The force being established, the reduction of the strength of the British imperial forces in S.A. from 11,500 to about 7,000 was announced in Nov. 1912. With regard to naval policy practically no progress was made. General Botha was fully alive to its importance and sought to educate his followers on the subject in several speeches. But in 1920 the situation remained as it was in 1910. The British Admiralty continued to use Simon's Town as headquarters of the Cape and East Coast Squadron. In 1921, however, the Government adopted the principle of the formation of a S.A. navy for home defence.

The policy to be adopted with respect to Asiatics had two aspects: (1) the treatment of Asiatics already in the Union and

(2) whether or not to permit further immigration. On the second question there was a determination on the part of the great majority of white S. Africans to prohibit the further entry of Asiatics alike on racial and economic grounds. They had the black man ever with them and they were determined as far as in them lay not to add another racial and disturbing factor. But there were already 150,000 Asiatics in the Union, and except for some 2,000 Chinese they were all British Indians. Of these fully four-fifths lived in Natal. They had gone thither at the invitation of that colony, where the sugar and tea plantations depended upon coolie labour. Indeed almost the only dissidents in the Union from the exclusion

¹ Only persons of European descent were allowed to become members of the Defence Force.

policy were the Natal planters. On the question of immigration the Government of India, however, took a step which eased the situation. It was a vigilant champion of the rights of Indians settled in other parts of the Empire and it had been for years dissatisfied with the treatment of the coolies in Natal. In 1908 it had decided to prohibit the further importation of indentured Indians into Natal and it was at the request of the Natal authorities that it permitted the system to continue until July 1911, when it finally ceased. This left untouched the question of voluntary immigration, which among the coolie class was never great. The position in the various provinces of the Union differed. In the Orange Free State as a result of a rigid exclusion policy constantly enforced there was no Indian question; in the Cape province Indians enjoyed equal rights with whites—political and municipal, not only in theory but in practice. But comparatively few Indians were attracted to the Cape and in that province the question was not acute. The Cape Immigration Acts of 1902 and 1906 sufficiently guarded the province from the influx of undesirable elements. In Natal the matter was much more pressing. There the Indians considerably outnumbered the whites and besides the coolie class included many Bombay Mohammedans (often misnamed "Arabs" in S.A.), keen and enterprising traders. Measures restrictive of Indian enterprise had been passed by Natal and in that province they had no political rights. They however possessed the municipal franchise and, as in the Cape province, had unrestricted rights to own and occupy land. In the Transvaal the Indians had neither political nor municipal rights nor were they allowed to own land, save in specially assigned locations. The Indians in that province were mainly Moslem traders, who had found a favourable field for their activities in the development of the country which followed the discovery of the Rand gold mines. For years the Indians in the Transvaal had been subjected to many restrictions; it was in this province that feeling against them was most bitter and the agitation against them most strong. The position held by white S. Africans was plainly stated by Gen. Smuts at the Imperial Conference of 1917. What he then said was strictly applicable to the situation in 1911 when the Union Parliament first took up the subject.

In S.A. there has been this fundamental trouble [he said], that the white community has been afraid of opening the door too wide to Indian immigration. We are not a homogeneous population. We are a white minority on a black continent, and the settlers in S.A. have for many years been actuated by the fear that to open the door to another non-white race would make the position of the few whites in S.A. very dangerous indeed. It is because of that fear . . . that they have adopted an attitude which sometimes has assumed the outward form, although not the reality, of intolerance.

Save that among many of the whites in the Transvaal the outward form of intolerance was also its reality, this was a fair statement of the position of white S. Africans. They feared, or a considerable proportion of them feared, being swamped by Asiatics, and, especially in the Transvaal, they greatly feared Indian competition in trade. On its part the Government, of India, when the Union began legislating on the subject was ready to acquiesce in an exclusion policy, but sought in return to secure fair treatment for the Indians already in the Union. And by "fair treatment" the Government of India meant in the long run political and municipal rights—weapons by which the Indians would have effective means of self-protection. In 1911 and again in 1912 Immigration Restriction bills were introduced into the Union Parliament, but the bills were dropped, a wider measure being announced for 1913. In Oct. 1912 Mr G. K. Gokhale, one of the most influential of Indian politicians, visited S.A. on "a mission of peace" and in Nov. went to Pretoria as the guest of the Union Government to confer with them on the forthcoming legislation. Mr. Gokhale's object was primarily to secure concessions for the Indians already in S. Africa. This was also the main object of Mr. M. K. Gandhi, who had first gone to S.A. in 1893 to conduct a law suit, but had stayed there and become the leader of the Indians in Natal and the Transvaal.

In June 1913 the Union Parliament passed an Immigrants Regulation Act, the chief purpose of which was to prevent the

further entry of Asiatics into the Union. This was done not *eo nomine* but by ministerial certificate. Wives and young children of domiciled residents were allowed to enter, and also registered Indians who might be temporarily absent from S. Africa. The Act further restricted Asiatics to the province in which they were resident. This restriction of movement, and the poll tax of £3 levied on all ex-indentured Indians in Natal—a tax unequal and uncertain in its incidence—caused great dissatisfaction among the Indian community. Under Mr. Gandhi's leadership (Mr. Gokhale had returned to India) they adopted an attitude of passive resistance, but this was succeeded by strikes at Durban and at the collieries and plantations. Then, to assert the right of Indians to move from one province to another, Mr. Gandhi put himself at the head of some 2,700 Indians who started to march past Majuba to Johannesburg. About 500 were stopped at the Natal border, the rest got some distance into the Transvaal before they were turned back. Mr. Gandhi was arrested and convicted on several charges, e.g. he was sentenced to nine months' imprisonment for abetting a strike of coal miners. But the situation could not be met simply by repressive measures. An Indian Inquiry Commission was appointed and, on its recommendation, the Natal poll tax was abandoned and certain concessions made as affecting the recognition of Indian marriages. These changes were made operative by the Indian Relief Act, 1914. More important was the so-called Smuts-Gandhi agreement of the same year. General Smuts as Minister of the Interior was in charge of the legislation affecting Indians, and, seeking a statesmanlike solution of the difficulty, he approached Mr. Gandhi. The negotiations succeeded and the arrangement reached was set forth in letters exchanged between Mr. Gorges (then secretary to the Ministry of the Interior) on behalf of Gen. Smuts, and Mr. Gandhi and dated June 30 1914. The essence of the agreement was the assurance by Gen. Smuts that existing laws would be administered "in a just manner and with due regard to vested rights." This was at the time interpreted by the Indians, by the Government of India and by many of the whites in S. A. to mean that the rights which Indians were entitled to exercise under the laws as existing in 1914 could not be restricted by fresh legislation. Mr. Gandhi, conceiving his mission in Africa ended, returned shortly afterwards to India.

It is convenient here to summarize later developments of the Indian question before turning to the main stream of S. A. history. Mr. Gandhi in a farewell letter, published in the *Rand Daily Mail* of July 20 1914, had assured the Indians that the settlement then reached did not preclude them from fresh agitation for the removal of other disabilities: for their part a large section of the whites agitated for further restrictions upon Indian activity. Friction inevitably arose, but during the World War untoward incidents were avoided. A definite settlement of the immigration question was reached at the Imperial Conference of 1918 when a reciprocity resolution was accepted which declared it to be "an inherent function of the governments of the several communities of the British Commonwealth, including India, that each should enjoy complete control of the composition of its own population by means of restriction on immigration from any of the other communities." In accepting this resolution on behalf of the Union Mr. Burton declared, justly, that S. Africans had found the Indians "good, law-abiding, quiet citizens" and that it was the duty of the Government to see that they were treated "as human beings, with feelings like our own, and in a proper manner."

What was the "proper manner" was still a point of contention. After the Smuts-Gandhi agreement Indians applied for and obtained new licences to trade, and in the Transvaal formed private companies with limited liability for the purpose of acquiring land and fixed property—the Transvaal law of 1885 which prohibited individual Indians from acquiring land not applying to corporate bodies. This action by the Indians was denounced by the white community in the Transvaal as a flagrant violation of the Smuts-Gandhi compact, to which the Indians replied that it was one of their vested rights and that

such companies had been formed before the agreement was made. There were in fact three such companies in 1913; by March 1910 the number registered had grown to 370, with a total capital of £479,000. Early in 1910 the Krugersdorp municipal council brought the matter to an issue, nominally on the trading question, by obtaining an interdict from the Supreme Court at Pretoria, prohibiting Indians from occupying a certain trading "stand" in the town. This led to the appointment of a parliamentary select committee. As the result of its investigations an Act (No. 37 of 1910) was passed by the Union Parliament which, while confirming the right of Indians to the occupation of land for trading purposes which they then held, prevented the further acquisition of land by Indians through private companies.

The Act of 1910 pleased neither party. It was noteworthy that in the Transvaal, where numerically the Indians were few, feeling against them was much stronger than in Natal, with its large Indian population. The explanation was to be found in the fact that whereas in the Transvaal nearly all the Indians were traders—many of them merchants owning large businesses and formidable competitors with white traders—in Natal the great bulk of the Indians were Madrassi of the agricultural and labouring classes, and save in fruit and vegetables did not enter largely into trade. Moreover, large numbers of the Indians in Natal were S. A. born and could hardly speak any Indian language. The agitation in the Transvaal against the "Asiatic menace" led in Feb. 1920 to the appointment of the Asiatic Inquiry Commission specifically charged to consider the question of trading rights and land ownership by Indians. The sittings of the Commission were held in public, the Government of India being represented throughout by Sir Benjamin Robertson, a man with unrivalled knowledge of the history and facts relating to Indians in S. Africa. The Commission issued an interim report in May 1920 recommending that steps be taken to aid the repatriation of as many Indians as desired to leave the country, and some few thousands did return to India. The final report of the Commission was issued in March 1921. The chairman was Sir J. H. Lange, a judge of the Supreme Court, and all the commissioners were men of experience, animated with the wish to do justice. Their inquiry had the merit of bringing out the facts and dispelling the belief that the Transvaal was menaced, numerically, by an Asiatic invasion. They also made clear the fatuity of the proposals put before them for the compulsory expropriation of the whole Indian population, or of "squeezing them out" by multiplying restrictions on their activities. Their recommendations were however significant of the strength of white feeling on the subject. They proposed alterations in the law which would secure Indians from being refused trading licences arbitrarily or on the ground of race; they opposed compulsory segregation, but advocated a system of voluntary separation by "attraction" to desirable residential and trading areas. They opposed the repeal of the Act of 1910 and went further by proposing that in Natal the right of Asiatics "to own land for farming or agricultural purposes should be confined to the coast belt, say 20 to 30 m inland." On this last point Mr. Duncan Baxter, one of the four commissioners, dissented, describing it as retrograde and a breach of the conditions of recruitment. The Government of India also at once lodged a protest against this recommendation, holding that it was not only a breach of the conditions under which Indians were recruited but also a breach of the Smuts-Gandhi agreement. The Union Government took no action on the Commission's report in the 1921 session of Parliament, but Mr. Patrick Duncan, who had become Minister of the Interior, indicated his sympathy with a proposal to allocate separate and distinct areas for occupation by the Indians of Natal.

The Government of India, while still seeking the removal of particular grievances, adhered to its wider view that only by the grant of equal rights could Indians in the Dominions be fully protected. At the Imperial Conference held in June-Aug. 1921 the Indian delegates pressed for the recognition of this principle and it was accepted by the representatives of Canada, Australia and New Zealand. But the S. A. delegates, of whom the chief

were Gen Smuts and Sir Thos Smartt, declined to subscribe to the resolution which declared that it was desirable that "the rights to citizenship" of Indians lawfully domiciled in other parts of the Empire "should be recognized." They regretted "their inability to accept this resolution in view of the exceptional circumstances of the greater part of the Union." Direct negotiations between the Governments of India and of S.A. to reach a more satisfactory position were not precluded. That the Union delegates rightly interpreted the feeling of most white South Africans was shown by an ordinance passed at this time by the Natal provincial council to prevent any Indians in the province acquiring in future the municipal franchise. This ordinance was disallowed by the Union Government. At the Cape at the same time an Indian, Dr Abdurrahman, a well-known member of the Cape Town municipality, was also a member of the provincial council.

The first step taken by the Union Government in regard to the relations between the white and native races was the decision that the control of all regulations made by local authorities affecting natives should be exercised not by the provincial councils but by the Government through the Native Affairs Department, a decision tending towards a much-needed uniformity of

policy. While the Government were considering what principles should guide their action public attention in 1911-2 was chiefly focussed on one aspect of the question, assaults by Kaffirs on white women. On the Rand in the first half of 1911 three Kaffirs were shot by white women whom they had attempted to assault. This shooting followed the commutation, in Jan. 1911, by the High Commissioner (Lord Gladstone) of a death sentence on a Rhodesian native convicted of an attempt to assault a white woman. This action roused much indignation against the High Commissioner who, however, met his critics fairly and won their respect. But feeling was intensified by the acquittal in Aug. 1911, by a Rhodesian jury, of a white man who had shot dead a Kaffir. (This led to the making of a special jury list for the trial of such cases, the ordinary jury not being trusted to administer impartial justice.) In all during the year ending March 31 1912, there was in the Union alone (i.e. Rhodesia excluded) 85 cases of outrages upon Europeans by natives, as compared with 60 during 1910. On the Rand the evil was attributed in part to illicit liquor selling and in part to the fact that the mine labourers were without their women-folk, and a petition signed by 52,000 Rand residents (presented to Parliament May 1912) asked *inter alia* for the provision of compounds in which natives should be permitted to keep their wives, as well as for facilities for training native female servants and for the importation of European domestics.

A commission, appointed in June 1912 on the motion of Sir Thomas Smartt, enquired into the prevalence of sexual assaults, and the extent to which they were attributable to economic and social factors. This commission was presided over by Mr. Melius de Villiers, ex-chief justice of the Free State and included four ladies, one from each province. On its report remedial measures were taken, such as provision for wives in the compounds. It was shown that one cause of the evil was the undue familiarity with which many white women treated male natives employed by them as domestic servants. The measures taken had a good effect, and assaults of the character stated became fewer.

On the larger question as to the place which the Bantu should hold in the community there was much heart searching. There was on the part of the whites agreement on one point only—the dependence of agriculture and industry on the manual labour of the native. The situation was complicated by the fact that the whites had not only the native to deal with but a very large number of coloured persons with a greater or less proportion of white blood—the well-known "Cape Boys." These people not only competed with the whites in skilled labour, but a good many of them had entered the professions as lawyers, doctors, journalists, land surveyors, etc. The pure African was following their example, and both the coloured and native peoples were learning the power of coöperation. They had their own newspapers, their own political and trade organizations,

and were quick to learn from the methods of the whites. Especially powerful was the influence of education and Christian missions. Many natives made great sacrifices to obtain education. For educational facilities they had to rely chiefly upon the missionary societies. The provincial councils were not generous in their expenditure in this respect though the total expended on native education rose from £81,000 in 1913 to £137,000 in 1918. More than half the total sum was spent by the Cape province. In regard to higher education the Union Government took a somewhat more liberal attitude and gave its support to the South African Native College at Fort Hare.

The desire of the natives, or the more vocal section of the natives, to escape from European tutelage was seen in a growing inclination, particularly in the Transkeian territories, to secularize education and to obtain a larger share in its management. This desire for "self-determination" was also seen in the setting up of many churches independent of European control, a movement fostered by intercourse with the negro churches of the United States. Of these native separatist churches perhaps the most influential was the "Ethiopian Church of South Africa." Their leaders joined in the demands of the "Native National Congress," an organization claiming to represent the Bantu peoples of S.A., in demanding redress of grievances and in especial the removal of the colour bar which existed in all the provinces except the Cape. A deputation from this body came to England in 1910 "not to demand independence, but admission into British citizenship."

Such were the aspirations of educated men among the coloured and native races; the more extreme, among whom communist doctrines had gained a hold, raised the cry of "Africa for the Africans." The loyalty of the natives and the valuable services they rendered during the World War went to show that the extremists were not an immediate danger. But the natives also during the war got a new idea of their power. Bantus in Rhodesia, the "Cape Boys" from the Union served as combatants in the E.A. campaign—and they saw that the heaviest fighting there fell to black troops. A new situation had arisen, one of the most noteworthy being the development of a race, as distinct from tribal, consciousness.

The problem as it presented itself to the Union Government was how best to secure the future for the white race in S.A., surrounded as it was by a black population five or six times its numbers. The Government would have had to face the bitterest hostility of the Dutch community, and of a considerable section of the British in Natal and the Transvaal had they attempted to remove the colour-bar in those provinces or in the Free State, had the Boers had their way the colour-bar would have been set up in the Cape province. Gen. Botha did not subscribe to the principle of Cecil Rhodes—"equal rights for all civilized men." Yet he and his colleagues acknowledged that it was the duty of the State to help forward the native on the path of efficiency and civilization, in opposition to the standpoint of the extreme Dutch Nationalists that there was no room for the advancement of the native save at the expense of the white man. The point of view of the Government was that the natives should be aided in such a manner that they should not come into competition with the whites. The proposal which attracted most support was to keep blacks and whites in separate areas, while still employing natives for labour on white enterprises. The plan was feasible; it was for example being worked in Basutoland under the Colonial Office. In that territory white settlement was forbidden, but thousands of Basutos went on contract to the gold-mines or to farms in the Free State. And there were already native areas in the Cape, such as the Transkei, where, under white officials, the natives possessed some share in the administration. It was in this direction Gen. Botha looked for a solution of the problem. In a speech in Parliament (May 9 1912) he stated that "the time was coming when the native question would have to be considered most seriously in the direction of keeping whites and natives apart and preventing their intermingling. They would have to fix attention closely on the question of segregation, while treating everyone with absolute

justice" The segregation plan received the support, among many others, of Sir Matthew Nathan, an ex-governor of Natal, and Gen. Hertzog. But it was opposed by those who, like Mr. P. W. Schreiner and Mr. Patrick Duncan (a leading member of the Unionist party), regarded it as both wrong and impolitic to put hindrances in the way of the advancement of the natives in civilization and industrial efficiency. Mr. Duncan in a striking pamphlet published in Oct. 1912 ("Suggestions for a Native Policy") admitted the dangers foreseen by the segregationists, but believed the remedy to be in European immigration on a large scale. "Nothing else," he declared, "will save S.A. for the European race." But to immigration on a large scale the Dutch community was definitely opposed, and it was not till 1920 that the Government made any strenuous effort to attract white settlers to the country.

A motion brought forward at the Unionist Congress in Johannesburg (Nov. 21 1912) to commit the party to the policy of segregation was defeated, the previous question being carried by 91 votes to 7. Opinion being so divided the Union Government found great difficulty in shaping its native policy. As a temporary measure a Native Land Act was passed in 1913 which prohibited the further acquisition of land by natives or from natives—an Act which led to vehement protests from native associations and leaders of native thought, while a legal decision was obtained that the provision of the Act did not apply to the Cape province. The Act had set up a commission, under the chairmanship of Sir William Beaumont, which had for its object the ascertainment of what land areas should be allocated to natives and those from which they should be excluded. The commission reported in 1916 and a Native Affairs Administration bill was introduced in 1917, chiefly as a means of ascertaining public opinion, native as well as white. It embodied the principle of separate areas in rural districts. After exhaustive consideration Parliament in 1920 passed a Native Affairs Act which was in effect a half-way segregation measure. The Act, for which Gen. Smuts was largely responsible, was based on the principle that the white man is the permanent and predominant factor in the civilization and government of S. Africa. But it was not repressive to the black man. It set aside areas for the exclusive occupation of the natives in which they would have greater opportunities than before for obtaining local self-government, it opened the way to a system of representative native congresses which would express authoritatively native opinion on intended legislation, and it held out the prospect of the development of native institutions parallel to but separate from those of the whites. In short Gen. Smuts, the great advocate for the union of the two European races in S.A., was equally earnest in his efforts to keep the streams of white and (nascent) black civilization apart. A feature of the Act of 1920 was the establishment of a permanent Native Affairs Commission to deal with the position of natives in urban areas, education and the Pass Law system, in all of which matters it was admitted that the natives had not received fair treatment. The Act was regarded by the white community—Dutch extremists apart—as a piece of constructive statesmanship, and its policy received the approval of the most responsible leaders of the natives. But danger lay in the inflammable language and actions of less responsible, and less educated agitators, working on the mass of their fellows, scarcely emerged from barbarism, and in the equally pernicious utterances of the white extremists. Events in 1920-1 showed the peril attendant on any mishandling of the native question.

The promotion of trade and agriculture occupied much of the energies of the people and Government. A prolonged drought—lasting from Oct. 1911 to Nov. 1912—the most severe experienced in S.A. since 1862, affected chiefly Natal, the Transvaal and the Transkei. The severe losses sustained forced attention to the need of more scientific farming and to irrigation works, upon which the Government expended £500,000 in 1912. In 1919 there was another very serious drought involving the country in an expenditure of £16,000,000. This led to the appointment of a commission in 1920 to enquire into drought, soil erosion and other allied prob-

lems. One result was to emphasize the need of water storage in connexion with irrigation. In Oct. 1912 a State Land and Agricultural Bank began operations in the Union, and a similar institution was established in Rhodesia.

Much diversity of view existed as to the tariff policy of the Union. Early in 1912 a commission, of which Sir T. M. Cullinan was chairman, appointed to enquire into the conditions of trade and industries reported in favour of increased duties on wheat, flour, sugar, tea, clothing and furniture, declaring that it was "not only necessary that a policy of protection should be adopted, but that there should be continuity of policy." Two influential members presented minority reports in favour of the "open door." Rhodesian feeling was in favour of a lower tariff, and it was suggested that Rhodesia might withdraw from the Customs Union rather than bear greater fiscal burdens. At Johannesburg on Nov. 19 1912 Sir Thomas Smartt declared that a plank in the Unionist party's platform was a tariff primarily for revenue purposes, combined with a policy for the encouragement of industries for the general benefit and the extension of the existing imperial preference. This was, in the main, the solution adopted. Tariffs and rebates were fixed by various Acts of Parliament passed between 1914 and 1919, designed to afford relief to home manufactures, the majority newly established. An Industries Advisory Board was set up in Oct. 1916, consisting for the most part of business men, and early in 1917 a Scientific and Technical Committee was instituted. There followed in 1921 the creation of a Board of Trade and Industries, and a definite policy of industrial development was undertaken by the Government. But Mr. F. S. Malan, Minister of Mines (and then acting Prime Minister) addressing the convention of the Federated Chamber of Industries at Port Elizabeth (July 25 1921) declared that the Government had no intention of "going in for an out-and-out protective policy." And Col. Reitz (Minister of Lands) told the sugar planters of Zululand that "the consumer must be protected. Higher tariffs would mean dearer prices."

One great department of state, the Railways and Harbour Board, was required by the Act of Union to be run with due regard to agricultural and industrial development and not as a producer of revenue for extraneous purposes. The Board built needed railway lines and undertook harbour works, though nothing material was done to enlarge the docks at Table Bay, a matter which provoked strong protests from the citizens of Cape Town. Mr. Sauer, the minister in charge of the department—whose budget was separate from that of the general budget of the Union—took an independent view of his duties and as early as July 1911 differences arose between him and his colleagues, especially with Mr. Hull, the Finance Minister. Mr. Hull had also to meet the attacks of Mr. Merriman, the most accomplished parliamentarian and ablest financier in the House of Assembly and a very candid friend of the Ministry. Mr. Merriman denounced the Government's financial proposals as predatory and extravagant, while Mr. Hull alleged that railway expenditure was incurred without Treasury sanction—that there had been a tendency to regard the railway and harbour administration as something for which the Government had no collective responsibility. General Botha admitted that the Cabinet had not been sufficiently consulted in railway matters and on May 18 1912 Mr. Hull resigned. A reconstruction of the Ministry was postponed until after the close of the parliamentary session (June 24), when the chief changes made were the appointment of Mr. Henry Burton (an ex-Cape minister), to the Ministry of Railway and Harbours, while Mr. Sauer became Minister of Agriculture, an office which Gen. Botha had combined with the premiership.

The differences between Mr. Hull and Mr. Sauer were shortly afterwards forgotten in consequence of the attitude taken up by Gen. Hertzog, who now began publicly to assail the principles upon which the Union had been established. To what extent Hertzog was supported or restrained by ex-President Steyn is uncertain; but Steyn, whose opinion would have been decisive with a large section of the Dutch community, did nothing publicly to counter-

Trade and Tariffs.

The Two Streams Policy.

act the rekindling of the fires of racial bitterness. The by-election campaign at Albany, caused by the resignation of Sir Starr Jameson, brought about a crisis. General Botha, and with him Gen. Smuts and the majority of the Dutch members of the Cabinet, had definitely accepted the British connexion, and the position of S.A. as a self-governing member of an Imperial Commonwealth, with corresponding responsibilities, and, knowing that peace between the two white races was essential to the prosperity of the country, he was an ardent advocate of the closest cooperation between them. On both these points Hertzog was violently opposed to his colleagues. His motto "South Africa first" meant in fact Dutch supremacy. In a speech at Nylstroom (Oct. 1912) he characterized Sir Thomas Smartt (who had succeeded Jameson as leader of the Unionist party) and other prominent members of the Opposition as "undesirable political foreign adventurers," and at Rustenburg, on Dec. 8, he declared that imperialism appealed to him only when it was useful to S. Africa. He had a short time previously pronounced in favour of the Dutch and British in S.A. remaining "two nationalities flowing each in a separate channel." General Botha though he publicly dissented from Gen. Hertzog's views was desirous if possible to avoid an open breach, but after the Rustenburg speech action was unavoidable. On Dec. 12 Col. Leuchers, Minister of Public Works and a Natal member of Parliament, resigned as a protest against Hertzog's "anti-British and anti-imperial sentiments." Botha then intimated to Hertzog that his resignation would be acceptable, but Hertzog refused to move. Botha met this difficulty by tendering his own resignation, Dec. 13, and was at once asked by the governor-general (Lord Gladstone) to form a new Ministry. This he had accomplished by Dec. 20, the new Cabinet being composed of the same members as the old except for the omission of Gen. Hertzog and Col. Leuchers (the latter replaced by Sir Thos. Watt, another Natal member). The death of two ministers—Mr. Sauer and Mr. Fischer—during 1913 necessitated a further remodelling of the Cabinet. Mr. N. J. de Wet became Minister of Justice and Mr. H. C. Van Heerden Minister of Agriculture.¹

The cleavage in the ranks of the ministerialists (the S.A. party) became complete in 1913. It was soon apparent that the appeal to Dutch racialism had considerable support, notably in the O.F.S., and some 10 or 12 members of the House of Assembly elected as supporters of Gen. Botha turned to Hertzog as their leader. At the party conference opened at Cape Town on Nov. 30 Gen. de Wet nominated ex-President Steyn as "leader of the party outside Parliament, with power to nominate the Prime Minister." On this proposal being defeated the malcontents left the conference in a body and in Jan. 1914 a new party under Hertzog's leadership was formed. It took the title of the Nationalist party.

The year 1913 and the opening months of 1914 were, however, as notable for labour unrest as for political differences. The disturbances in Natal due to the opposition of the Indians to the Asiatic legislation of the Union have already been recorded. They caused no such trouble as attended disturbances on the Rand, which began with a strike of the white miners at the New Kleinfontein mine in May 1913. The strike was nominally on the question of hours, but it was symptomatic of a determination of Labour to gain greater control over industrial conditions. There was, too, a revolutionary wing to the movement, and the extremists seemed likely to carry with them the mass of the men.² The two antagonistic views were afterwards sharply put by Gen. Smuts and Mr. Creswell, the latter the leader of the parliamentary Labour

¹ The year 1913 witnessed the death of other prominent S. Africans—Sir Gordon Sprigg, four times Prime Minister of Cape Colony, Sir Richard Solomon, High Commissioner in London of the Union, and Dinizulu, the son of Cetewayo. Sir Walter Hely-Hutchinson, formerly Governor of Natal and of Cape Colony, also died in 1913. Sir R. Solomon was succeeded as High Commissioner by Mr. W. P. Schreiner, who died in 1919. Sir Edgar Walton was appointed High Commissioner in 1921.

² The white employees in the mines were almost equally divided between those born in S.A. and those born in the United Kingdom. The foreign born were scarcely 5%.

party. Smuts declared the movement to have been "a conspiracy against constituted order." Mr. Creswell declared that there was "a conspiracy (of the Govt.) with capitalists to run the country in their own interests." Neither view gave a satisfactory explanation of the facts. The strike extended, negotiations for a settlement failed, feeling ran high and by the end of June the Government had drafted 2,000 troops into the Benoni district, the centre of unrest, and some 20 m. E. of Johannesburg. The leaders of the strike had chosen a time when the Union was without a regular armed force of its own. The citizen army provided by the Act of 1912 was not yet formed, while the militia and volunteers had been disbanded as from July 1, and the permanent force—the S.A. Mounted Riflemen—provided for in the Act of 1912, had only begun training in April (1913). British regulars were therefore drafted into Johannesburg, where serious rioting followed a demonstration by the men in Market Sq. (July 4). The strikers seized the electric power station, and during a night of terror burned down the Park railway station and the offices of the *Star* newspaper. Several persons were killed and many injured in conflicts with the police and military. The next morning Gens. Botha and Smuts intervened and opened negotiations with the strikers. While these were going on dynamite explosions occurred and the mob attacked the Rand club. The negotiators succeeded in reaching agreement and at night the strike was declared "off", one condition being the reinstatement of the men at the New Kleinfontein mine. But it was difficult to appease the mob and there was further rioting on July 6. In all some 20 persons were killed and 250 injured. A grave element of danger was the excited condition of the native labourers on the Rand mines and it was in part consideration of what they might do if the riots continued that drew the authorities and the strike leaders together. The situation continued anxious, as extremists were calling for a new and general strike. But on July 31 the executive of the Federation of Trades decided by 65 votes against 18 not to call a general strike. An official inquiry into labour conditions was then instituted, but in Jan. 1914 new trouble arose. A policy of retrenchment on the railways was resented by the men and a general strike proclaimed for Jan. 14. It was, according to the official view, an attempt by the Trades' Federation to control the railway administration. The Government acted promptly (Gen. Smuts was at the time both Minister of Defence and Minister of the Interior). Martial law was proclaimed and 20,000 troops mobilized and concentrated on the Rand. Ten prominent Labour leaders—not including Mr. Creswell—were arrested and secretly deported, illegal action for which the Government subsequently obtained an Act of indemnity. In Parliament Gen. Smuts justified his action on the ground stated, namely that the leaders of the men were engaged in a revolutionary conspiracy. The action of the Government had, in any case, prevented a renewal of the rioting of 1913 though a large number of outrages occurred. Ameliorative measures were then tried and during 1914 an Industrial Disputes Act was passed. It set up machinery intended to render easier the settlement of disputes and this Act was followed in subsequent years by other measures—such as the Factory Act of 1918—designed to improve labour conditions.

In 1914 Lord Gladstone's term of office as Governor-General and High Commissioner expired and he returned to England shortly before the outbreak of the World War. His successor was Mr. Sydney Buxton, who on his appointment was created a viscount. Lord Buxton assumed office in Sept. 1914.

The outbreak of the World War tested S.A. in a manner in which no other British Dominion was tested. Twelve years only had passed since the Boers had been in arms against Great Britain, they had long and bitter memories and all the ties of kinship, affection, a common tongue and a common heritage which powerfully influenced the British in S.A. were in them lacking. The spirit of racialism had revived, and a large number of the Dutch were led to believe that the war was no concern of theirs and that S.A. should remain neutral. A smaller section actively sympathized with Germany and a few prominent Boers had entered into rela-

Effect of
World
War.

tions with the Germans in S.W. Africa. The German Government counted with some confidence that S.A. would stand aloof from the contest. It was misled. The attitude of Gen. Botha and of his colleagues was never in doubt. Botha, Smuts and the other Dutch members of the Government represented all those Boers who were not only faithful to the new allegiance they had solemnly recognized in 1902, but who were sincerely convinced that by the subsequent grant of responsible government to the ex-Dutch republics and the establishment of the Union, S. Africa's interest, as a self-governing dominion, was to stand side by side with the other members of the British Commonwealth.

The test as to the part S.A. would play in the World War soon came. On Aug. 7 1914, the Imperial Government telegraphed to the Union Government that "if they desired and felt themselves able" to do so, the seizure of such parts of German S.W. Africa as would give them the command of Lüderitzbucht, Swakopmund and the wireless stations there, would be "a great and urgent imperial service." And two days later the British Cabinet suggested that another expedition might be sent later to Windhuk, where there was a long-distance wireless station. On Aug. 10 Gen. Botha replied that he and his colleagues cordially agreed to cooperate with the Imperial Government and that the military operations indicated would be undertaken by the Union Government. General Botha had already intimated—on the day that war was declared—that the country would undertake its own defence, thus setting free for duty elsewhere the imperial garrison in S. Africa. It was not however until Sept. that Gen. Botha publicly announced the intention of the Government to send an expedition against German S.W. Africa, though this intention was communicated to Gen. Beyers on Aug. 13 and discussed at a meeting of the principal officers of the defence force held on Aug. 21. On that occasion Beyers expressed approval of the measures proposed. While their intentions in regard to S.W. Africa were meanwhile regarded as confidential, the fact that the Government had ranged itself on the side of Britain had been known from the first day of the war and had greatly excited the Dutch Nationalists. Some of them saw in it the opportunity they had eagerly awaited of regaining the independence of the Boer republics, some were already aiding the Germans in S.W. Africa. The decision of the Government to take the offensive against the Germans precipitated, but was not the originating cause of, the rebellion. German secret agents, too, had been busy, but their intrigues at most only served to fan smouldering fires of revolt. Botha submitted the resolution authorizing an expedition to German S.W. Africa at a session of Parliament on Sept. 9. It was bitterly denounced by Hertzog and his followers, who declared that the

Rebellion of 1914.

Union should remain neutral, but it passed the House of Assembly by a large majority on Sept. 10 and by the 14th had received the approval of the Senate. On Sept. 15 Gen. Beyers made clear his true attitude. He resigned his post of commandant-general of the Union Forces, affirming that "by far the great majority of the Dutch-speaking people of the Union" disapproved the expedition against German S.W. Africa. Botha's reply was that he himself would take command of the Union forces and personally command the operations against the Germans. On Oct. 9 Lt.-Col. Solomon G. Maritz, the commander of the Union forces—about 1,600 men—on the German frontier, was in open rebellion, on Oct. 23 de Wet was in rebellion in the Free State, the next day Beyers and Maj. J. Kemp were in rebellion in the Transvaal. The movement was concerted, though the plans for concerted action failed. Of the four rebel leaders named, Maritz was the least important and the only one proved to have been in treasonable relations with the Germans before the World War began. The evidence against Beyers of collusion with the Germans through Maritz after the war had started was conclusive, but there is no evidence that he rose in revolt out of sympathy with them. As one of their ablest leaders in the Anglo-Boer War he enjoyed a great reputation with the Transvaal Boers. Kemp also was known to them as an efficient soldier who had been one of De La Rey's chief lieutenants in the Anglo-Boer War. Kemp was now an officer of the Defence

Force. De Wet was the most famous fighting general of the Free State Boers. All the men named desired to translate into action the policy which Hertzog advocated, and which they believed Steyn approved. In the opinion of a judicial commission¹ which later enquired into the rebellion (whose report was issued in Dec. 1916) Gen. De La Rey plotted a rising as soon as the war broke out. The chief aim was to restore the Dutch republics—if not to establish a completely independent S.A. Republic. At the time it looked as if De La Rey was being dragged into rebellion by Beyers and Kemp. It is certain that they depended upon De La Rey to give the word to the Transvaal burghers to rise. Whether or not through infirmity of purpose when De La Rey was brought to Treurfontein (Aug. 15) to address a meeting of burghers which had been called, in his name, with the intention of immediately starting a revolt instead of the expected words he advised his hearers to remain calm and wait events. De La Rey two days previously had been called to Pretoria by Botha and there had had a prolonged interview with Botha and Smuts who had exhorted him to use his unrivalled influence in the western Transvaal in the interest of peace.² And without question the burghers, though mystified, obeyed De La Rey and dispersed quietly to their homes. Then came the public announcement of the expedition against German S.W. Africa and De La Rey went to Cape Town to attend the session of Parliament, of which he was a senator. Meanwhile the Citizen Force of the western Transvaal was gathered at Potchefstroom and Beyers and Kemp arranged with De La Rey that he should return N. and address the burghers in camp on Sept. 15. On the evening of that day, at Pretoria, Beyers announced his resignation. In the morning of the same day he had received a messenger from Maritz who brought word that "all was ready" on the border. De La Rey had reached Johannesburg from the Cape; Maritz's messenger was sent by Beyers to bring him to Pretoria and late in the evening the three set out to go by motor to Potchefstroom. The revolt was to be started the next morning. The way led through Johannesburg and the car was ordered to stop by armed police, who were looking out for a gang of criminals who had escaped in a motor. Beyer's driver disregarded the summons to stop and drove on. The police patrol fired and De La Rey was shot dead. The dramatic death of De La Rey disorganized the conspirators' plans. It deprived them of the one man who could have raised the whole of the western Transvaal against Botha and the one man whose military talents might have matched those of Botha and Smuts. It accounted for the delay in the rebellion, for the interim protestations of loyalty made by Beyers and de Wet's declaration that he wanted to act constitutionally. In de Wet's case there was no evidence that he had been mixed up with Maritz's intrigues with the Germans until after the World War had begun, his was pure discontent with the existing regime.

An illuminating light on the mentality of the rebels was the profound belief that many of them entertained for the "visions" of a certain Nicholas Van Rensburg, a farmer of Lichtenburg, who had served in the Anglo-Boer War under De La Rey, at which time his reputation as a seer was established. Van Rensburg's sincerity was doubted by few—and he seldom professed to understand his own visions, which were of a true Delphic character. One of them was held to foretell the struggle in Europe and to indicate the victory of Germany "the grey bull" which defeated a red bull (England) in bloody combat. Another concerned Gen. De La Rey and with this vision was associated the number 15, which Van Rensburg beheld on a dark cloud from which issued blood. This man's visions and the faith they

¹ Composed of three judges of the Supreme Court, namely J. H. Lange (chairman), M. W. Searle, and F. A. Hutton.

² From Gen. Botha's account of the conversation De La Rey appears to have been in a distracted frame of mind. That he wished S.A. to break away from the British Empire and proclaim its independence is beyond question, and he saw in the World War an opportunity to achieve this object. He was very much under the influence of the "prophet" Van Rensburg (see later). By several observers of his conduct at this time De La Rey was believed to be mentally deranged.

inspired among the burghers—and in none more strongly than in De La Rey himself—were cleverly worked upon by the conspirators—it was because of the visions that the Aug. and Sept. meetings were called for the 15th of the month. But the rebellion rested on more solid foundations than visions. As has been stated the moving cause was the desire of the Boers to regain independence, while support for the rebellion was largely gained by the assertions of Beyers and others that there would be no fighting and that Botha was secretly on their side.

News of Maritz's open revolt reached Beyers and Kemp on Oct. 12; two days later de Wet was in conference with Beyers at Pretoria and final plans prepared. But Maritz was crushed before the others could take effective action. General Smuts, as Minister of Defence, had taken over the full direction of affairs from headquarters. Colonel Coen Brits was sent to deal with the traitor and did so effectively, in an engagement at Kakamas on Oct. 24 Maritz's force was broken into small and fugitive bands and he himself compelled to take refuge over the German border. Meanwhile both Botha and Smuts were urgent in their efforts to prevent bloodshed in the Free State and the Transvaal. They turned to ex-President Steyn as the one man whose word could deter the rebels from executing their purpose. On Oct. 11 Botha telegraphed to Steyn—who, in poor health, was living at his farm Onze Rust, near Bloemfontein—informing him of the treason of Maritz, and saying "A word from you will go far." Steyn refused to speak the word. Not that he approved the action of Maritz, but because "I shall have to tell the people that I most strongly disapprove of the policy of the Government respecting an attack upon German W. Africa . . . that as far back as three years ago I warned you against such a policy and that on the outbreak of the European war I had again repeated that warning to Gen Smuts. . . . As a result of that policy a number of officers and men, who as far as I know were loyal, have become rebels." To this Botha replied that the Government's policy was "not only supported but demanded by the vast majority of the population of the Union," and that, moreover, he possessed proofs that Maritz's plot was formed long before the Government's decision was made. He ended with a moving appeal to Steyn to speak a word "to warn our people against treason, against the everlasting stain that anything of the kind would be upon our national honour, and against the incalculably fatal consequences." No sign in reply came from Onze Rust. On Oct. 22 Botha again wrote to Steyn, informing him of the imminent revolt of de Wet, Beyers and Kemp. In this letter Botha referred feelingly to the outcome of an insurrection "headed by men who in the past have been our honoured leaders" and once more appealed to Steyn to turn those men "from the path of destruction where they now stand." Botha suggested that Steyn should summon de Wet, Beyers and Kemp to a conference at Onze Rust, and now at length Steyn acted. From Oct. 23 onward, and after hostilities had begun he used his efforts to bring the rebel leaders to reason. But only after he had been beaten did Beyers go to Onze Rust, nor was it until he, too, had been defeated that de Wet showed any desire to visit Steyn. The ex-President himself publicly uttered no word. It may here be added that two years later Steyn died and the restraining hand which he had laid upon the extreme manifestations of Dutch racialism was removed. Hertzog, who had not joined the rebels, and had indeed given Steyn some help in trying to induce de Wet and Beyers not to proceed to hostilities, was then free to develop his demand for separation from the Empire.

General Botha delayed operations against Beyers and de Wet as long as there was any possibility of avoiding bloodshed, indeed the Government was sharply criticized for allowing de Wet undisturbed to overrun the northern part of the Free State on pretext of carrying on private negotiations. Rebel activity in the Transvaal at length compelled action and Gen Botha himself took the field against his old colleagues. If that action finally destroyed his influence with part of the Boers, it won the support of many others and it was one of the disappointments of the rebels that so many

men of their own blood sided with the Government. On Oct. 27 Botha dispersed a rebel commando led by Beyers at Commissie Drift, S. of Rustenburg. Even after this encounter—in which the casualties were two or three men wounded—efforts were made to avoid further fighting, but unavailing. Beyers crossed into the Free State and on Nov. 7 a fight took place at Gruss Drift, on the Vet river, in which some 400 rebels were taken prisoners. It was after this defeat that Beyers, under a safe conduct, sought a belated conference with Steyn, a conference which led to no result. Meanwhile de Wet had been active in the Free State, his burghers freely pillaging all whom they pleased. At Vrede on Oct. 29 he denounced "the ungodly policy of General Botha," the "miserable pestilent English" and described the S.W. expedition as "a dastardly act of robbery." On Nov. 9 he seized Winburg, he had refused to go to Onze Rust to see Steyn. Smuts rightly gauged the mentality of de Wet in stating that unless he were "convinced by force" he would not listen to reason. On Nov. 12 Botha defeated de Wet's main commando, some 2,000 strong, at Mushroom Valley, 18 m S.E. of Winburg. After this de Wet was willing to go and see Steyn, but the Government was convinced that the time had gone by for the rebels to "extort peace terms" and on Nov. 17 Smuts informed Steyn that now unconditional surrender was required, on the basis of very lenient terms already announced. Pressed by the Government troops de Wet doubled and redoubled and finally, with some 50 followers, turned due W. hoping to make German territory. But he was overtaken about 100 m W. of Mafeking—his tired horses being no match for the fleet armoured cars chasing him—and surrendered, Dec. 1 (1914) to Col. Brits. A few days later the end came for Beyers. After his visit to Steyn he had rejoined his commando, and after an engagement at Bultfontein on Nov. 16 made N. intending to re-enter the Transvaal. On Dec. 8, in the Hoopstad district, he was once again defeated. With some 25 burghers Beyers reached the Vaal river near Zand Spruit closely pressed by a party under Field-Cornet P. H. de Necker. While the rebels put up a delaying fight, Beyers and one companion tried to cross the river on horseback. When fired upon they dismounted. Their horses managed to gain the further bank, but Beyers and his comrade, though they escaped the bullets, were carried away by the current and drowned. A week later (Dec. 16) the last of the rebel commanders, Fourie, was defeated and he surrendered. The rebellion was over.¹

Altogether about 10,000 men had been in armed rebellion, while the number of their sympathizers was very considerable. In their ranks were three members of Parliament. The casualties on the Government side were 132 killed and 277 wounded. Of the rebels over 5,700 were either captured or surrendered—their casualties are not known, and many returned home during hostilities under assurances that by so doing they would not be prosecuted. Only one man, Fourie, an officer of the Citizen Force who appears to have deserted while on active service, suffered the last penalty. He was tried by court-martial and shot on Dec. 20. The rest of the rebels were leniently treated. De Wet, in June 1915, was sentenced to six years' imprisonment and a fine of £2,000, Kemp was sentenced to seven years' imprisonment and a fine of £1,000. Others received lesser sentences and few, if any, served their full term, de Wet, for instance, and 118 others were released in Dec. 1915 in time to spend their Christmas at home.

During the insurrection Hertzog's name had been freely coupled with that of the rebels, and in the parliamentary session of 1915 he made himself their advocate. He was no rebel, neither,

¹ Major Kemp had been sent, on Nov. 2, by Beyers on a mission to get arms and ammunition from Maritz. Kemp, who had with him some 800 men, appeared at Kuruman on Nov. 8 where he obtained supplies from the town-folk. Followed up by loyal forces he made his way to German territory and joined Maritz at the end of November. In Jan. 1915, in company with Maritz, he reappeared, attacked Upington and was defeated. At the same place on Feb. 3, with over 500 men he surrendered to Col. (later Maj.-Gen. Sir) J. L. Van Deventer, while 100 of Maritz's men surrendered at Kakamas. Maritz and his immediate following withdrew to German S.-West Africa. Not wanted there Maritz went to Angola and to Lisbon.

The Appeal to Mr. Steyn.

De Wet captured.

he maintained, were de Wet, Beyers and their following. Their action was only "an armed protest" against the invasion of German S. West Africa.¹ Nor did Hertzog and his parliamentary supporters modify their attitude, they sought to gain at the polls what the rebels had tried to gain arms in hand. But Gen. Botha had no difficulty in enrolling thousands of Boer volunteers for the campaign in German S. West Africa, the force raised for that purpose was composed almost equally of Dutch and British S. Africans. The campaign ended in the surrender of the Germans on July 9 1915, and on his return home Botha received a triumphal welcome from Boer and Briton alike. Popular feeling against Germany had become intense with the sinking of the "Lusitania," which led to serious riots, in Johannesburg alone damage to German property estimated at £500,000 was done.

After the conquest of German S. W. Africa Nationalist hostility was aroused by the beginning of recruitment for service in

*Forces

Service.*

Europe. The response to the appeal for volunteers, considering the hostility of the Nationalists, was excellent. First to last the Union (apart from forces used in suppressing the rebellion) raised 146,515 men for service in the World War, and of these over 30,000 served in Europe and 43,000 in E. Africa. These figures refer only to whites. Including the native labour contingents and the coloured combatant corps from the Cape provinces the total personnel of the S. A. forces on war service was 231,501. The casualties numbered 18,642, including 6,606 dead.

None knew better than Gens. Botha and Smuts how deeply they were distrusted by a large section of the Dutch community.

*General
Election,
1918.*

The general election held on Oct. 20 1918, fought on the issues raised by the rebellion, gave a very fair indication of the strength of the Dutch irreconcilables. Botha had appealed to the electors to sink their differences and "see the war through." Out of a total of 130 seats in the House of Assembly the S. A. (Botha's) party gained 54, the Nationalists (Hertzogites) 27 and the Unionist (mainly British) party 40. Labour, out of favour after the industrial upheaval, gained only three seats and there were six Independents (all anti-Hertzogites). Most of the Nationalist members were returned for constituencies situated in the districts where the rebellion had been. The luck of the ballot was with Botha and the Unionists for the figures of the poll showed the Nationalist strength to be greater than the number of seats secured. The figures were: South African party 93,374 votes, Nationalists 78,301, Unionists 48,484, Labour 25,305, Independents 12,020. Some 75% of the electors voted.

As a result of the election Botha was dependent for continuance in office on the support of the Unionists, and this was ungrudgingly given. There was some talk of Sir Thomas Smartt and other leaders of the Unionists joining the Ministry, but this was not done. The cordial support given by the Unionists to Gen. Botha was the more valuable as the Nationalists continued their agitation and increased their demands. Hertzog's efforts were powerless to affect the policy of the Cabinet but they led to increased bitterness in S. Africa. The Government had, nevertheless, no difficulty in securing volunteers for service in German E. Africa. The appointment of Gen. Smuts as commander of the British forces there entailed his absence from the Cape, an absence prolonged by his selection early in 1917 as a member of the Imperial War Cabinet in London. This was a serious loss to Botha in the conduct of home policy.

After Steyn's death (in Nov. 1916) Hertzog became more openly hostile than ever to the imperial connexion. At Stellenbosch in May 1917 he declared that S. Africa's autonomy

*Republicans
Propa-
ganda.*

(*selfstandigheid*) entitled her to remain neutral in the war and that no real self-government could exist without independence of all other countries, including Great Britain. "The only bond that binds us together," he said, "is our common King but under him we each stand separately and independent of each other." But even "the common bond"

¹ In a proclamation issued by Beyers and de Wet on Oct. 29 1914, they signed themselves "generals of the protesting burghers."

was irksome, and the logical outcome of Hertzog's policy was seen in the adoption by the Nationalist party of republicanism as a plank in their programme, to be achieved "by steady constitutional pressure." The opposite policy was seen that year in operation in London. General Smuts was sitting in the Cabinet with equality of status with that of the ministers of the United Kingdom, and the Imperial War Conference of that year (1917) declared the Dominions to be "autonomous nations of an Imperial Commonwealth with an adequate voice in foreign policy." The adoption of republicanism in the Nationalist platform was strongly resented in the Union and on the motion of Mr. Merriman—who voiced very accurately the feelings of most of the Cape province Dutchmen—a motion condemning republican propaganda was carried (June 18 1917) by 72 votes to 21. The propaganda, however, grew in virulence. There was, said Gen. Botha in 1918, an agitation on foot to establish a republic by violent means.

It will be seen that throughout the World War S. A. had been divided by bitter racial strife. It was not, however, the traditional clash between Briton and Boer, but a combination of Boer and Briton against a section of the Boer community, and this marked an advance on old conditions. Nor were all those who gave Hertzog their votes really prepared to follow him to all lengths. But the defeat of Germany brought no respite in the Nationalist agitation—it rather increased, nor did it require much astuteness for Hertzog to fix upon President Wilson's declarations in favour of self-determination as a weapon. The last half of 1918 was, however, noteworthy in S. A. for other than political happenings. In the influenza epidemic which swept over the world S. A. suffered very severely. Influenza attacked both the white and coloured population and was most severe in the Cape peninsula. A total of 54,809 deaths were registered in Aug.-Dec. 1918. Of these, 11,510 were among whites and of these 6,004 occurred in the Cape province. (There was a recurrence of the epidemic in 1919, but in a milder form.)

As soon as the World War ended Gen. Botha was summoned to London² where he joined Gen. Smuts. They represented S. A. throughout the peace negotiations and both were signatories of the Treaty of Versailles, under which S. A. and the other British Dominions became original members of the League of Nations. The counter-measures of the Nationalists failed. No sooner had hostilities ceased than the central committee of their organization sent a note to President Wilson expressing their desire to lay before him their aspiration that the principle of self-determination should be applied as much to the S. A. people as to "other small nations." Mr. Wilson declined to interfere. General Hertzog was at heart most concerned to regain independence for the ex-Dutch republics. Thus in a debate initiated by Sir Thomas Smartt on the republican propaganda in the House of Assembly in Feb. 1919 he maintained the right of the Free State to break away from the Union. At the opening of the session in Jan. one of his henchmen, Mr. Tielman Roos, in the debate on the resolution congratulating King George on the victory of the Allies, had moved an amendment declaring that peace could only be maintained by the "complete application" of the principle of self-determination enunciated by the Allied and Associated Powers. This amendment had been defeated by 73 votes to 20.

Hoping to get some advantage out of the struggle going on around the Peace Conference table in Paris Gen. Hertzog and certain of his colleagues determined to visit Europe. Hertzog held that the question of the Union as a whole becoming a republic was a matter in which Great Britain had no voice, but meanwhile Great Britain might "redress the wrong done to the ex-Dutch republics by restoring to them their freedom." He and his colleagues would lay their case before the Prime Minister, Mr. Lloyd George. When it was announced that a Nationalist deputation would leave for England, trouble arose. The crews of the mail steamers intimated that they would not put to sea if Gen. Hertzog and his colleagues were passengers. This difficulty was met by the offer to bring them over to England in a British

² In Botha's absence Mr. F. S. Malan was acting Prime Minister.

man-of-war. Hertzog, however, realized that that would render him ridiculous, eventually he and his friends sailed in a Dutch vessel to New York, whence they took passage to Europe. They saw Mr. Lloyd George, they visited Paris, and they returned to S.A. unsatisfied. Mr. Lloyd George pointed out to them, among other things, that the restoration of the Dutch republic was not a matter to bring before the Imperial Government, the Union of S.A. was a self-governing state and could speak only through its own constitutionally chosen Ministry.

The Treaty of Versailles having been signed (June 28 1919) Gens. Botha and Smuts returned to S. Africa. A few weeks later Gen. Botha, whose health had been indifferent for some time, died (Aug. 27) after a very brief illness. In him S.A. lost one of her greatest sons, and the Empire a man who, whether as friend or foe, had been large minded, sincere and whole-hearted. With regard to Botha's successor Lord Buxton, the governor-general, had no hesitation. Gen. Smuts was the inevitable choice. In Sept. at a special session of Parliament, the peace treaty with Germany was debated, and a resolution passed asking King George to ratify it on behalf of the Union. In this debate and on many other occasions Gen. Smuts dwelt on the enhanced position S.A. had acquired as a result of the World War; she had not only become an equal member of the British Commonwealth, with a voice in the direction of its foreign affairs, but a separate entity in the comity of nations. Greater freedom it could not possess, it was mistress of its own destinies, but, so he argued, it was not open to the Union to break away from the British connexion.

The war had ended, economically S.A. had suffered from it less than might have been anticipated, and a period of trade expansion had set in. Smuts, both in generalship and in diplomacy, had been the greatest figure which the British Dominions had thrown up during the conflict. He was presently called upon to get the verdict of his own people on his policy and actions, for by the constitution, another general election was due. It was held in March 1920 in circumstances somewhat unfavourable for the Ministry. Though on imperial questions the Unionist party and the S.A. party held the same views, there were many points on purely domestic issues on which they did not agree and they opposed one another at the polls, often too when a Nationalist was contesting the same seat. There were several triangular and even some quadrilateral contests—caused by Labour candidatures. And the election showed that the Nationalists, determinedly narrow in their outlook—for many back-veld Boers the world outside S.A. counted as nothing—had gained strength. There were 134 seats to be filled as against 130 in 1915. The Nationalists came out the strongest single party with 45 seats; the S.A. party held 40, the Unionists 25, while Labour gained the remarkable number of 21 seats. Three Independents completed the list. The Nationalists were jubilant and with the help of the Labour members hoped for great things. Gen. Smuts was in a difficult position but he resolved to meet Parliament and carry on the Government. This could only be done with the help of the Unionists—and that help was given to Smuts as freely as it had been given to Botha. Even so, the margin of votes was exceedingly small and would have disappeared had not several of the Labour members on the main issues also supported the Ministry. As it was Smuts went through the session with remarkable skill and succeeded in passing more than one important measure—among others the Native Administration Act (see above).

The evidence that the election had afforded of the strength of the Nationalists could not however be ignored, nor was it possible that in the existing state of parties Parliament could continue to do its work efficiently or the country be at peace. Some way out must be found. Considering his race, it is not a matter for wonder that Smuts tried first to see if an accommodation could be reached with the Nationalists. A reunited party which would have the support of the whole Dutch community was a tempting prospect. Negotiations went on for some time; finally in Sept. 1920 a herecining (re-

union) conference was held at Bloemfontein. It failed, and its failure might have been foreseen. On various points the Nationalists or the S.A. party were prepared for compromise, but when the test came it was seen that there was no bridging the gulf which separated them on essentials. Gen. Smuts and his party held firm to the principles of the unity of the Union and the preservation of the ties which linked the Union to the Empire. The Nationalists, on their side, refused to abandon the republican plank in their platform.

Gen. Smuts consequently turned for support elsewhere. In a manifesto issued on Sept. 29 and addressed to "all right minded S. Africans, irrespective of race or party" he asked them "to join a new party which shall be strong enough to safeguard the permanent interests of the Union against the disruptive and destructive policy of the Nationalists." This was an open bid to the Unionists, nor were they indisposed to respond. Their fundamental principles were those of Gen. Smuts and his followers. But when at the conference of the S.A. party, held on Oct. 27, a resolution was adopted directing the head committee of the organization to take the necessary steps not for the creation of a new party, but for "an expansion of the S.A. party," some difficulty was created. The Unionists, who represented the bulk of the British section of the community, had, though with natural regret, been prepared to make a new combination, but they disliked the idea of simple absorption into a predominantly Dutch organization. These feelings were expressed at the Unionist party conference at Bloemfontein early in November. Counsels of patriotism prevailed and at a meeting between the Unionist executive and Gen. Smuts at Johannesburg on Nov. 27, a complete agreement was reached. The Unionists joined the S.A. party, which retained its name. Nor was it an unfitting title, though it would become meaningless if the fusion of the two races came about, and the old distinction between Boer and Briton obliterated. This possibility was precisely what the Nationalists (and also a few British extremists) most dreaded while it was the goal to which Smuts looked forward. Speaking in London on May 22 1917, he had declared "we want to create a blend out of various nationalities. We want to create a new nation and that is the South African nation . . . I am hopeful that . . . we shall in the end succeed and create under our South African sun a new type in the world."

Having drawn together the supporters of "national unity of the European races and the economic development of S.A. along peaceful lines" Gen. Smuts made a new appeal to the country, backed by the whole strength of what had been the Unionist party. Smuts fought the election on the republican issue. With the alternative thus nakedly put the Nationalists took alarm. They knew that success for them on such an issue was impossible and therefore they tried to confuse the people, and snatch a victory on other grounds. Severance from the British Empire, the turning of the Union into a republic, was not, they declared, their immediate object, rather was it an ideal which they hoped to attain in a remote future. This manoeuvre deceived no one. Even if the Nationalists did not ardently desire a complete rupture with Great Britain they did want to secure at once complete ascendancy in the ex-Boer Republics. During the election campaign Hertzog was induced to put the case baldly. Heckled at a meeting at Roodebank in the Standerton district he said that "even today (1921) he would accept a republic in the Transvaal and Free State and those Englishmen who objected might retain their British citizenship. If they had any grievances they would be represented by a British diplomatic agent." He admitted that if his wish were granted and difficulties arose the country would be in exactly the same position as before the Boer War.

The election was held in Feb. 1921 and resulted in a notable triumph for Gen. Smuts and the enlarged S.A. party. But it was significant that the Nationalist vote increased and that on balance of losses and gains they held two more seats in the new than they had held in the old Parliament. The distribution of parties was as follows:—South African 76, Nationalist 47, Labour 10, In-

**Botha's

**The 1921
Election.**

**Herecining
Efforts.**

dependent.¹ The 76 seats held by the S.A. party compared with 40 in the old S.A. party and 25 in the old Unionist party. The gains of the enlarged party had been at the expense of the Labour candidates. But an analysis of the poll showed that Smuts had rallied to his side many doubtful voters besides those transferred from Labour. Nor could the Nationalists claim that those who voted for Labour candidates favoured their propaganda; there were in the Transvaal bitter contests between Nationalist and Labour candidates. In considering the figures of the votes cast it should be remembered that nine S.A. party candidates were returned unopposed, whereas only one Nationalist (Gen. Hertzog himself) was not opposed. It is also noteworthy that the Nationalists' successes were almost entirely in rural and remote constituencies, decisive evidence that their strength lay in the back-veld Boers. The figures were: S.A. party 138,042 (an increase of 10,455 compared with 1920), Nationalists 104,602 (an increase of over 8,000), Labour 28,083 (a decrease of over 12,000).

Following upon the election there was a reorganization of the Cabinet in which Sir Thos. Smartt became Minister for Agriculture, Mr. Patrick Duncan Minister for the Interior, and Mr. J. W. Jagger Minister for Railways and Harbours. Another leader of the late Unionist party, Sir Edgar Walton, was appointed High Commissioner in London. In June 1921 Gen. Smuts, Sir T. Smartt and Col. H. Mentz (Minister of Defence) came to London to attend the Imperial Conference. In regard to matters affecting the internal affairs of S.A. the most delicate question discussed by the conference was the status of British Indians (see above). While the ministers were still in London the question of the future of Rhodesia advanced a stage. A deputation had been invited to discuss with the Colonial Office a plan for ascertaining whether Rhodesia was prepared to take a referendum upon a definite scheme of self-government (see RHODESIA). Largely however as the result of the general election in the Union in Feb. 1921 the party in Rhodesia which preferred to join the Union had again grown in strength. The Rhodesian deputation saw Gen. Smuts early in Sept., immediately after his return to Cape Town, when it was made clear that though the admission of Rhodesia as a province of the Union would be welcomed, it was a matter for the Rhodesians to decide.

In the 1921 election campaign the Nationalists sought to evade the main issue partly by assailing the policy of the Government on native affairs. That policy has already been outlined, by Nationalist orators addressing the back-veld Boer the conciliatory measures adopted were denounced as "cooperating with niggers", by Nationalist orators addressing audiences in the Cape province—where the native had the vote—the segregation clauses of the Act of 1920 were denounced as evidence of the bias of the Government against the Kaffirs. This method of electioneering had elements of danger, for discontent among considerable sections of the natives was pronounced. The chief ground of complaint was in regard to their economic position. The natives had been quick to learn the lesson of the strikes of white labour on the Rand and in 1917 and subsequent years there had been strikes and native disturbances at Johannesburg and other cities. There were also many evidences of political and religious ferment. Serious disturbances at the Lovedale missionary institute in April 1920,² were followed on Oct. 23 of the same year by a disastrous collision at Port Elizabeth. In the last-named case the native labourers had struck for higher wages and their leader, Masabalala, president of the Native Workers Union, had been arrested and refused bail. An angry crowd gathered before the court house and fire was opened upon it by the Europeans who feared an

attack. Rioting and incendiarism ensued and for a time it looked as if Port Elizabeth would be at the mercy of the natives. In all over 20 persons (including one European) were killed and 40 injured. The action of the natives was condemned by many of their leaders, such as Dr. Rubusana, an ex-member of the Cape provincial council and by Mr. Jabavu,³ a graduate of London University, who, while calling for the remedy of grievances, denounced the "Bolshevist propaganda" permeating the native mind. An investigation made by a commission appointed by the Government tended to show that the authorities at Port Elizabeth had mishandled the affair, and that bloodshed might have been avoided had Masabalala been granted bail. It was a cause for angry recriminations later when Nationalist candidates for Parliament appeared on the same platform as Masabalala.

A greater tragedy followed at Bulhoek, near Queenstown on May 24 1921. For months several hundreds of natives known as Israelites, proselytes of one Enoch Ngijima, who gave himself out as the prophet Enoch, had been allowed to remain at Bulhoek and they had become a menace to the community. Whether or not earlier action might have averted the calamity is not certain; in this case the Government acted with great forbearance. But at length it became imperative that the Israelites should be compelled to return to their homes, and forces were moved to Bulhoek to be in readiness for eventualities. Enoch proved intractable and his followers proved themselves possessed of all the fanaticism of dervishes. On May 24, when preparations were being made for their removal, large numbers of them, though destitute of firearms, charged the troops, and some 400 were killed or wounded before their ranks wavered and broke. On this occasion the soldiers had no option but to fire, the Israelites, though their reckless charge exhibited only fanaticism, had also shown military skill and had dug trenches and prepared ambushes for the troops. Their dispersal was a necessity. Neither did responsible native leaders approve Enoch's teachings.

The Bulhoek tragedy was, however, regarded by the leaders of the natives as the outcome of unjust economic laws. The case against the Government was put by Mr. Selby Maimang, the president of the Industrial Commercial Workers Union—a union which embraced nearly all the native and coloured trade organizations in South Africa—at its meeting at Cape Town in July 1921. Mr. Maimang said that the land laws of the country were to blame for the catastrophe. Enoch's following had fallen victims to bad influences brought about by bad administration. Coloured workers were smarting under irritating disabilities in every walk of life. Mr. Maimang, a representative of moderate opinion among the natives, reprobated the useless stirring up of passions, declaring it to be the duty of the Union to educate all non-European workers to guard their own interests. Organization was essential, they could only ward themselves against exploitation by a distinct band of comradeship. As to that many European employers were already convinced that combination among the natives engaged in industries was a factor which they could not ignore.

The decline in trade which became noticeable in the middle of 1920, and was acute in the first half of 1921, added to the difficulties of the industrial problem. It affected both white and coloured labour severely and caused renewed agitation on the Rand, while diamond mining came almost to a standstill.

Lord Buxton's tenure of the office of governor-general and high commissioner came to an end in 1920. In very difficult circumstances he had carried out his duties with firmness and in a manner which won the esteem of all classes, including the Nationalists. He identified himself with the interests of S. Africa. On giving up office he was granted an earldom (Oct. 21 1920), and on his return home served as chairman of the committee appointed to inquire into the future government of Rhodesia. Prince Arthur of Connaught was chosen as the new governor-general and high commissioner. He reached the Cape on Nov. 17—ten years after his father, the Duke of Connaught, had opened the first session of the Union Parliament.

¹ Son of Tengo Jabavu (d. 1921), editor of *Imvo (si Bantu)*, an influential native newspaper, which he had founded in 1884.

¹ These figures include the results of recounts and of two by-elections in the Transvaal, necessitated by ties in the voting at the general election. At two by-elections for Cape Town constituencies in Sept. 1921 Labour candidates won, bringing the Labour members of Parliament to 12 and reducing the S.A. Party to 74.

² The students attempted to burn down the college buildings and murder the professors. The rioting began with complaints as to the quality of the bread served, which was the same for whites and blacks.

DEFENCE AND MILITARY INSTITUTIONS

The establishment of union in S. Africa in the year 1910 involved a fusion of the different military systems then obtaining in the four colonies which became original Constituent Provinces in the new amalgamation. These systems were as follows. The Cape Colony maintained a permanent force (the Cape Mounted Riflemen) together with a volunteer force and a cadet organization. The forces of Natal consisted of a military force, of much the same strength (3,000-4,000 men) and character as the volunteer force of the Cape and a reserve organized in rifle clubs, and included cadets again on much the same lines as those of the kindred organization in the Cape Colony. The two forces contained regiments of long standing and high reputation gained in many local campaigns and embraced all arms. These regiments retained their identity in the new forces. A volunteer force on modern lines, confined to the towns, except for two mounted regiments recruited from country districts, was the form of military organization which had been adopted by the Transvaal. This force, however, had only been in existence for seven or eight years at the date of union. In the same period an efficient cadet system had been instituted. In each of these three colonies a small permanent staff was maintained. The Orange Free State relied upon the burgher system based on universal male liability for service in time of war, a principle accepted indeed by all the four colonies, and reaffirmed in the present S. Africa Defence Act.

It was not until June 14 1912 that it was found possible to pass a law embodying the recommendations which had been made and the conclusions which had been arrived at after investigation, but upon this date the S. Africa Defence Act, 1912, was placed on the statute book. Field-Marshal Lord Methuen, then commander-in-chief of the British forces in S. Africa, evinced great interest in the matter of South African defence and assisted the local military authorities in the conferences and

deliberations which preceded the passing of the Act. By this Act every citizen between 17 and 60 (both included) is liable to render personal service in time of war in defence of the Union "in any part of South Africa." A permanent force is provided for, but in May 1921 an amending bill was before the House of Assembly, which if accepted would materially alter the composition and functions of this force.

Every citizen is liable to undergo, beginning in his twenty-first year, four years "peace training" in the Active Citizen Force, which constitutes the first line of defence. It is however permissible for any citizen to enter voluntarily for his "peace training" in any year between his 17th and 21st years (both included). The number of citizens to be trained in the Active Citizen Force is placed in the Act at 50% of the total number liable, but Parliament has power to increase this number. If the number required for training in any district is greater than that of its voluntary entries, a ballot may be taken to make good the shortage. After four years' "peace training" in the Active Citizen Force the citizen goes to Class A of the Citizen Force Reserve where he remains until his 45th year. A Coast Garrison Force is established, and service may be undertaken in that force as equivalent to Active Citizen Force "peace training." A similar concession is allowed to citizens who may elect to serve in the Royal Naval Volunteer Reserve which is part of the Royal Naval Reserve constituted under the Naval Forces Act 1903 (Great Britain and Ireland) and may be placed at the disposal of the Royal Naval authorities. Any citizen who at 21 has not been entered for service in the Active Citizen Force (or one of its equivalents) is compelled to serve for four years in a Rifle Association where he is taught to be "familiar with the use of military weapons of precision," after which he is included in Class B of the Citizen Force Reserve until his 45th year. Cadet service is compulsory, but a request from a parent or guardian that a boy "be exempt from cadet training" secures a certificate of exemption. Several special reserves are provided for in the Act, and one of these, the Veteran Reserve, was largely used in establishments within the Union during the period 1914-8. The National Reserve consists of all citizens who, liable to render personal service in time of war, do not belong to any other portion of the forces. The full establishments of the Active Citizen Force in 1914 represented a force of approximately 30,000 men. The periods of "peace training" are not more than 30 days in the first year and 21 days in each subsequent year with a maximum of continuous training (in camp) of 22 and 15 days respectively.

The response to the first year's (1913) call for entries was striking, and 44,193 citizens entered voluntarily for training, producing a strength of 14,000 in excess of requirements. The following year saw the outbreak of the World War, and the annual registration in Jan. of all citizens who reach the age of 17 in the year has been in abeyance since Jan. 1914.

Immediately after the passage of the Defence Act in 1912 steps were taken to establish the military system for which it provided. The permanent force at its inception consisted of two portions. The staff was employed partly at defence headquarters and partly distributed in the 15 military districts of the Union. The South African Mounted Riflemen (five regiments and three batteries of field artillery) was, with the exception of the artillery, employed solely on police work, and divided into very small detachments on posts. The whole of the police force had in May 1921 been placed under the command of the commissioner of police, and the new military arrangements proposed in 1921 contemplated a reduced permanent force employed on military duties alone.¹

The complications introduced by the rebellion made it impossible to call out the whole of the citizen forces in the formations in which they strictly belonged, and, though a considerable number of units of the Active Citizen Force were called out by proclamation in the regular way, most of the Dutch members of the forces—many of whom were beyond the age of those in the Active Citizen Force—were specially embodied under the old commando system to which they had been formerly accustomed. Thus the whole of the Dutch-speaking units serving under Gen. Botha in the rebellion and German S. W. Africa were organized on a commando basis, the English speaking units being those of the Active Citizen Force. In the rebellion 30,000 troops (of whom 20,000 were of Dutch descent) were employed at a cost of £5,100,000 to the Union Government, and casualties to the extent of 132 killed and 242 wounded were sustained by the loyal troops. In German S. W. Africa 67,237 Union troops were engaged at an approximate cost of £15,000,000 and 127 lives were lost, the wounded amounting to 272.

¹ The S. African Mounted Riflemen, as a brigade, served in the rebellion of 1914, and at the close of the campaign in German S. W. Africa, but thereafter were retained in the Union, though many individual members of the force served with credit and distinction on many battle fronts.

At the conclusion of the campaign in German S W Africa the Union Government turned its attention to other fields in which assistance was needed. These were overseas, and the liability of S African citizens to military service did not extend to such distant spheres of activity. It was thus necessary to devise special measures to furnish troops composed of S Africans who were prepared of their free will to serve beyond the limits of S Africa.

In July 1915 the Imperial Government accepted the offer of the Union Government to furnish personnel for units for service beyond S. Africa. A director of war recruiting was appointed and recruiting was maintained until the Armistice in 1918. The following are the numbers of all the forces which were raised in the Union for the different campaigns in which South African troops took part—

The rebellion	30,000
German S W Africa	67,237
Overseas (France)	30,880
German E & Central Africa	47,521
For service in the Union	5,180

The achievements of the S Africans in France and their fortitude under hardship in the East African campaign are matters of history.

The coloured community in the Cape province had early expressed a strong desire to furnish a representative body of troops, and an infantry battalion of the Cape Corps was formed, and later a second battalion was recruited. The regiment after gaining valuable experience in E and Central Africa was sent as one battalion to Egypt and Palestine, where it served with credit. The natives of the Union, who throughout the war maintained an attitude of complete self-control and loyalty, furnished for non-combatant duties 35,000 men for German S W. Africa, 10,600 for France and 18,000 for E. and Central Africa. Some hundreds of natives lost their lives in the transport "Mendi" which was sunk in the English Channel.

While, as a consequence of the large number of men who, especially at the outset of the war, joined the British forces as individuals, a full statement of the casualties sustained by S Africa in the World War is not available, the following figures give some idea of the incidence of losses. In the S African Infantry Brigade in France nearly 15,000 casualties were sustained, of which some 5,000 were killed. In the Cape Corps which served in E Africa, Egypt and Palestine, the casualties in dead and wounded totalled 701. Disease and privation took heavy toll in East Africa and hundreds of men returned to the Union from the campaign in that country shattered in health. The Royal Naval Volunteer Reserve supplied and maintained a strong detachment for service in the Grand Fleet and naval establishments. Hospitals, camps, supply and ordnance depots, and veterinary hospitals were formed in S. Africa under Union control, and heavy purchases were made and vast amounts of supplies were forwarded to E Africa under Union military supervision on behalf of the Imperial Government.

As regards the future military arrangements of the Union the main provisions of the Act of 1912 have been accepted as sound, though methods will doubtless be reformed to a considerable extent. An amending defence bill in May 1921, in addition to important changes in the constitution and functions of the permanent force, provided for a resumption of registration, with retrospective effect as regards citizens who should have been registered in and since 1918, also for the working of the normal training system in 1922, and for a substantial increase in the period of continuous "peace training," as well as for increasing cadet efficiency, by additional expenditure of public funds and by extending the age for cadet service. The bill was, however, dropped in June 1921. (J J C.)

SOUTH CAROLINA (see 25 400*)—The pop. of the state in 1920 was 1,683,724, an increase of 11.1% over the previous decade, as compared with 13.1% and 16.4% during the two preceding decades. During the decade 1910-20 negroes increased from 679,161 to 818,538, or from 44.8% of the total pop. to 48.6%. The density was 55.2 per sq mile. The urban pop. was 17.5% of the whole, as compared with 14.8% in 1910. The pop. of Charleston was 67,957 and the decennial increase 15.5%, the white increase being 28.3% and the negro 4%. The white pop., increased by war industries, was 52.4% of the whole, con-

stituting a majority for the first time in about 200 years. The pop. and decennial increase for the other leading cities were as follows:—

	1920	1910	Increase per cent
Columbia	37,524	26,319	42.6
Greenville	23,127	15,741	46.9
Spartanburg	22,638	17,517	29.2
Florence	10,968	7,057	55.7
Anderson	10,579	9,654	9.5
Sumter	9,508	8,100	17.3

Manufactures—Textile mills paid very large dividends during 1917-20, and in addition doubled or trebled their capital. Wages rose greatly, but were cut 30 to 50% in the depression of 1920-1. The number of spindles in 1918 was 4,914,524; of operatives in 1919, 50,898, a decrease of about 4,000 since 1916, the bales of cotton consumed diminished from 972,000 in 1916 to 779,000 in 1918-9; capitalization that year was \$201,237,320. Almost half the motive power in 1920 was hydro-electric. Unionization has not proceeded far among textile workers, though skilled trades in larger places are generally organized. The State Board of Conciliation, created in 1916, arbitrates labour disputes on invitation or investigates them on its own motion or the order of the governor. Women are forbidden to work in stores after 10 P.M. or over 12 hours in one day.

Agriculture—The coincidence of the World War and a large cotton crop in 1914 demoralized farming. A law was passed forbidding the planting of more than a third of a farm's acreage in cotton, but was repealed before the next planting season. An enormous inflation of values soon followed and in turn was succeeded by a decline of prices from about \$0.40 to \$0.10 or \$0.11 in six months (1920-1), entailing great hardship. Legislation (1912) sought to stabilize agricultural prices by a system of state warehouses for holding products for a favourable market. Private capital has been extensively invested to the same end. The boll weevil became a serious menace in 1920 in the south-western counties. A packing plant with a daily capacity of 400 hogs was established in Orangeburg. Butter-making in cooperative creameries has made some progress. Under the law of 1920 extensive drainage projects were undertaken. Agricultural methods have improved, farm-houses are better, banks, which have increased in number and capital, finance the farmer directly at greatly lower cost than formerly charged by "hen merchants." South Carolina led all the states in 1917 in crop value per acre with an average of \$63. The value in 1918 was \$75. According to state Government estimate cotton covered in 1920 45% of the cultivated acreage and represented 50% of the value of the 13 leading crops. One million five hundred and thirty thousand bales were raised, the state's acreage being fourth and its production second in the Union. Corn, second in value, amounted to 42,370,000 bushels. Other crops were tobacco 66,950,000 lb.; rice 120,000 bu.; sorghum 1,500,000 gal.; peanuts 1,620,000 bushels. The average value of ploughed lands was \$61 per acre as against \$91 for the United States. Average monthly wages for adult male farm labour without board were \$1.80, next to the lowest for any state. During 1910-20 the number of farms increased from 176,434 to 192,693, improved land from 6,097,999 ac. to 6,184,159 ac.; average value per farm from \$2,223 to \$4,946, average value per acre from \$29.02 to \$76.70.

Education—School legislation since 1910 included an Act for compulsory school attendance in 1919 throughout the state, increased state additions to local funds, calculated to ensure after 1920 a seven-months' term in the poorest districts; night schools for adults; consolidation and grading of rural schools, with transportation for children; an increased number of high schools, special teachers and inspectors in rural and textile districts, greatly improved school buildings, enlarged facilities for agricultural, vocational and home economics training, state standard certification of teachers and enforcement of payment for tuition at state colleges by those able to pay. The most significant principle underlying the forward movement in education has been the recognition of the necessity of greater assistance from state funds and greater power in the state authorities as distinguished from the local divisions. Difficulties have been the lack of competent teachers to carry out the enlarged programme and maintain the higher standards, the shortness of the rural school term, and excessive local authority to do or neglect to do what it pleases. The expenditure on common schools in 1918-9 exceeded \$8,000,000. Attendance in common schools in 1919-20 for whites was 226,005, for negroes, 231,980, total 478,045. There were in that year enrolled in the 36 colleges in the state 12,000 students, of whom a third were negroes.

The three most numerous religious denominations, the Baptist, Methodist and Presbyterian, have added materially during 1910-20 to their extensive work in higher education. All but 11 of the 36 institutions for higher education in the state were in 1920 under church control, and these institutions contained a thousand more students than all state and other non-sectarian institutions combined.

Social Legislation—Every attempt of forces of reaction to abandon a step in the large number of forward moves in social legislation since 1910 has been defeated, usually overwhelmingly.

*These figures indicate the volume and page number of the previous article

In 1912 race gambling was forbidden. In 1913 the penitentiary hospital was abolished as harmful to the health of the prisoners. The State Board of Charities and Corrections, created in 1915, was reorganized in 1920 as the State Board of Public Welfare. The state hospital for the insane was entirely remade, materially and administratively, during 1915-9. A school for the feeble-minded was established in 1918. The placing of orphans and homeless children was taken over by the state in 1920. In 1918 the Industrial School for Girls, a reformatory institution for white girls, was established and the reformatory for negro boys was reorganized. The probate judge in each county is constituted a juvenile court, and several cities have undertaken remedial work for juvenile delinquents and dependents. Penal and charitable institutions (including church and private charitable institutions) have been since 1915 under state inspection. Since 1918 diseased women prisoners of all classes are held until cured. The age of consent was raised in 1921 to 16 years. No city has acted upon the permission in 1915 to segregate whites and negroes by city blocks. Marriage licences were required by law in 1911 and registration of births and deaths in 1914. Medical inspection of school children was made state-wide in 1920.

Finance.—The budget system, concentrating responsibility on the governor and the chairman of the two legislative finance committees, adopted in 1919, has tended to economy and system, though the Legislature may disregard without any limitation the recommendations. The State Tax Commission, created in 1915, has improved the administration of the tax laws. The assessed taxable value of all property in 1920 was \$448,222,786, being from a fourth to a third of the market value. For the state government there was raised a revenue of approximately \$6,000,000, for county governments \$12,000,000, for common schools (local tax) \$8,000,000; and for municipal government between \$5,000,000 and \$6,000,000.

Political History.—The class feeling that has always been strong in South Carolina politics found violent manifestation during the governorship of Coleman L. Blease, who served two terms from 1911 to 1915. Blease's political tactics were calculated to appeal to the lower and less literate elements of the state, he quarrelled with the state Supreme Court, with the General Assembly, with other state officers and with the U.S. authorities. The Legislature was at all times controlled by his opponents, and probably more measures were passed over his veto than had been so passed in the case of all former governors combined. He startled a congress of governors at Richmond, Va., in 1912 by an open advocacy of lynching, and while governor he pardoned or paroled more than 1,500 criminals. At the time of his resignation (a few days before his term expired in 1915) he had freed all but 150 convicts, the number then said to be remaining in the institutions of the state. Almost his last official act was an order disbanding the state militia; this was promptly countermanded by his successor. Resigning without giving any explanation, he was succeeded for five days by Lt.-Gov. C. A. Smith. In 1918 Mr. Blease made a campaign for election to the U.S. Senate, taking extreme ground against the country's entering the war. He was overwhelmingly defeated. A progressive period began with the election of Gov. Richard I. Manning in 1914. A significant feature of the campaign was the support given to Prof. John G. Clinkscales in his advocacy of compulsory education. Gov. Manning's two administrations were marked by constructive legislation and effective coöperation with the national Government. Gov. Robert A. Cooper was elected in 1918 on a platform that made education its chief plank and frankly announced that as the result of progressive legislation taxes would be higher. He was reelected without opposition in 1920. His chief measures were the strengthening of the public schools, the creation of a budget system and the consolidation of management of charitable and correctional institutions. The Australian ballot was put in force (1921) in primaries, though not in the general election, the latter being merely a formal ratification of the former as the Democratic nomination is equivalent to election.

The World War.—Of the total of 78 Congressional Medals of Honour awarded, South Carolina received six. The total number of men sent by South Carolina into the war was 54,254, not including those who had enlisted before the United States declared war. The amount of Liberty and Victory loans and other Government securities bought was \$94,211,244, and \$3,027,740 was contributed to Red Cross and similar appeals.

BIBLIOGRAPHY.—Snowden (editor), *History of South Carolina* (5 vols. 1920); *Reports of S.C. Superintendent of Education, Treas-*

urer, Comptroller-General and Commissioner of Agriculture, Commerce and Industries, S.C. Statutes at large. (D. D. W.)

SOUTH DAKOTA (see 25,506).—The pop. of the state in 1920 was 636,547, as compared with 583,888 in 1910, an increase of 52,659, or a little more than 9%. The average density in 1920 was 8.3 per sq. mile. The rural pop. was 84% of the whole in 1920, against 86.8% in 1910, an increase of 27,460, or 5.4%. The urban pop. (cities with 2,500 inhabitants and over) was 101,872 in 1920 against 76,673 in 1910, an increase of 25,199, or nearly 33%. The pop. of Sioux Falls increased 79.7% to 25,176 in 1920. Its rapid growth is due largely to the opening of extensive packing plants, stock yards and factories. Aberdeen in 1920 had 14,537 inhabitants, Watertown, 9,400; Mitchell, 8,478; Huron, 8,302; Rapid City, 5,777; Yankton, 5,024; Lead, 5,013; and Pierre, the state capital, 3,209. The foreign-born white pop. in 1920 was 82,372, of which 16,807 were Norwegians, 8,569 Swedes, 5,083 Danes, 15,670 Germans, 11,191 Russians, 4,453 Canadians, 2,043 British.

Communications.—A panoramic picture of the surface of the state in 1921 would present many changes from one in 1910, but both pictures would have the appearance of a chess-board, of which the country roads, running a mile apart from E. to W. and from S. to N., would mark the squares. In the hills, near river beds, in the bad lands, and in uncultivated and thinly populated portions, the roads are not uniformly maintained. The law provides that they be 66 ft. in width. Each square mile of land is called a section and contains, including one half of the roads on the four sides, 640 ac. of land. The roads are still for the most part dirt roads. During the decade 1910-20 they were considerably improved by grading and elevating the centre. All of the 64 counties either have been actually engaged in the building of hard-surfaced roads or have started preparations for doing so. Advantage is taken of the Federal appropriations for highway purpose of which South Dakota's share was \$4,458,545. State and county have made heavy assessments. Over \$6,000,000 has been spent in building hard-surfaced roads. The state Legislature appropriated \$2,000,000 for the construction, in 1921, at Rapid City, of a cement plant with a daily capacity of 2,000 barrels. A system of state trunk highways is supposed to connect all county seats and all towns having a pop. of 750 and more. A law provides that every county must employ a county engineer whose occupation is the planning of better highways. The automobile, the truck and the tractor have become more common than horsed vehicles, and have awakened the farmers to the advantage of good roads, 117,320 automobiles, enough to carry comfortably all the inhabitants of the state at one time were licensed in 1920. In connexion with the improvement of the roads, mention should be made of the bridge which was being built in 1921, at a cost of \$1,500,000 across the Missouri river at Yankton, and which supplies the last connecting link of the Meridian Highway which crosses the state and extends from Winnipeg, Canada, to the Gulf of Mexico. Only about 300 m. of railway were built during the 10 years, 1910-20.

Agriculture.—There were 74,637 farmers in 1920, of whom 47,815 were owners, 26,041 renters and 781 managers. Many owners of the rented farms either lived on their farms or in the neighbouring towns, having rented to their prospective heirs. Though there were 74,637 farmers to 76,868 sq. m. of land, it is not the case that the great majority of the farmers occupied on an average a sq. m. of land each. All of the land area was not under cultivation, and among those who occupy the 34,636,491 ac. of agricultural lands outside of the corporate limits, the great majority of the farmers have each much less than the average, which is 454 acres. A minority, mostly west of the Missouri river, operate the large farms.

The farmers prospered during the 10 years, 1910-20. Their prosperity was evident in many other respects than the improvement of the highways and the large number of automobiles, trucks and tractors. Farm life underwent a rapid change. Electricity, telephones, rural mail delivery and consolidated school-houses added to the comforts and education of the people. Farm machinery was improved and bodily labour decreased. Many of the counties employ county agents, who are supposed to be highly trained agricultural experts. Because of the introduction of scientific methods, farm crops have become more varied and rotation of crops has become possible. The corn acreage in 1920 surpassed the wheat acreage, and the production of other grains and grasses increased. The introduction of alfalfa was especially noteworthy. Alfalfa was harvested three and four times a year. As a result, and also because of the large use of the silo, much more stock has been raised and more dairy products and eggs sent to market. The breeds of cattle, horses, hogs and poultry have been improved and many farmers raise only pure-blooded stock. A much greater number of farmers, as well as of city people, were in 1921 raising their own vegetables and fruits. Orchards and groves have increased in number and area. Because of many clusters of trees the unbroken prairie-like appearance of the farms has been modified. Farm values have more than doubled and the use of improved farm equipment has become much more exten-

TACNA-ARICA QUESTION.—Among long-standing disputes between states, the question of Tacna-Arica, between Chile and Peru, still remained unsolved in 1921. Its history can be summarized as follows.

The Treaty of Ancon, which, ratified on March 28 1884, put an end to the war of 1879 between Chile and Peru, was carried out in its entirety with the single exception of Clause 3, dealing with the fate of the provinces of Tacna and Arica. In 1881, when Peru first sued for peace, Chile, with an eye to the future safety of her frontiers, demanded the cession of three Peruvian provinces Tarapacá, Tacna and Arica. The Peruvian Government made no difficulty about the first-named, which passed definitely into Chile's possession, but they refused to consider the cession of the relatively valueless provinces of Tacna and Arica, on the ground that public opinion in Peru would never suffer it. To smooth the way for them Chile offered to purchase the territory in question for the sum, or equivalent, of ten million Peruvian *soles*, but the offer was rejected. The war therefore continued until 1882, when Chile succeeded in occupying the Peruvian capital. Chile again made the cession of Tacna and Arica a *sine qua non* for the signing of the peace treaty. The Peruvian Government's chief concern was to find a way of acceding without grievously wounding the national sentiment. Examples were not lacking in recent European diplomacy of a means of effecting this, France, especially, had had recourse to an expedient wherewith to save appearances and mask important transfers of territory, namely, Nice and Savoy in 1860 (Treaty of Turin), and the island of St. Barthélemy in 1877 (Treaty of Paris). That expedient consisted in inserting in the treaties whereby the territory was ceded a soothing stipulation for a plebiscite, which should decide, at some future date, its definite ownership. Comparison shows that the negotiators of the Treaty of Ancon, in drafting the clause concerning Tacna and Arica, followed closely enough the formulas provided by the Treaties of Turin and Paris. The clause runs as follows:—

Art. 3. The territory of the provinces of Tacna and Arica, bounded . . . etc., shall continue in the possession of Chile and subject to Chilean legislation and Chilean authorities for the term of ten years, reckoned from the ratification of the present Treaty of Peace. This term having expired a plebiscite shall decide by popular vote whether the territory of the said provinces is to remain definitely under the domain and sovereignty of Chile or continue to form part of Peru's territory. The country in whose favour the provinces of Tacna and Arica shall be annexed shall pay to the other ten million *pesos* in Chilean silver money or in Peruvian *soles* of equal fineness and weight.

A special protocol, which shall be considered an integral part of the present treaty, shall establish the form in which the plebiscite is to take place and the terms and periods in which the ten millions are to be paid by the country which shall remain owner of the provinces of Tacna and Arica.

Chile's contention subsequently was that this clause was inserted solely in order to allay Peruvian national resentment and so to make possible the conclusion of peace, that the plebiscite to which it refers was to be carried out under such conditions as to render inevitable the definite annexation of Tacna and Arica, upon which Chile had insisted from the first, that the sole purpose of the stipulated lapse of 10 years before the plebiscite should be held was to give the Peruvian people time to accustom themselves to Chilean rule, and that the sum of 10 million *soles* which would be paid by Chile was meant as compensation for the cession. Peru, on the other hand, maintained that the plebiscite clauses introduced into such treaties as those of Turin and Paris had not the disguised intention that Chile claimed, and that, even supposing they had, the plebiscite called for in the Treaty of Ancon was of a very different nature.

The period of 10 years had not expired before Peru took steps to secure the holding of the plebiscite, proposing conditions, which, as they included the restriction of the vote to the Peruvians born in the two provinces, proved unacceptable to Chile. Several years of fruitless negotiation ensued, and in 1901 Peru

severed diplomatic relations. Four years later she accepted Chile's invitation to renew their intercourse, and to seek with her neighbour an agreement based upon the interests and convenience of the two republics, but the Peruvian plenipotentiary, on his arrival at Santiago, made it clear that his Government desired no other agreement than such as would forward the carrying-out of the plebiscite under the same conditions proposed previously, and diplomatic relations were again broken off.

Notwithstanding her contentions as to the purely accommodatory nature of the clause in dispute, Chile always declared her willingness that the plebiscite should be held, provided the suffrage were not limited to Peruvians but extended to all the adult inhabitants of the provinces, including foreigners resident therein since a certain date, who could read and write, and that a representative of Chile, as the nation exercising sovereignty over the territory, should preside over the commission controlling the proceedings. For her part, Peru insisted that the 10 years stipulated for the holding of the plebiscite was a *maximum* period, and that since its expiry in 1894 Chile no longer exercised such sovereignty *de jure*, and could not therefore justly claim to preside. Chile, on the contrary, held that the term was intended as a *minimum* period.

Diplomatic intercourse having been resumed, Chile, in 1910, made definite proposals for the holding of the plebiscite in accordance with her contentions. Peru refused, and once more broke off relations.

In 1920 Peru made formal request for the revision of the Treaty of Ancon by the 1921 Assembly of the League of Nations, but later withdrew her demand, reserving the right to renew it at a future Assembly. The problem of Tacna and Arica stood in 1921 therefore in much the same position as at any time subsequent to the Treaty of Ancon, though towards the end of the year suggestions for arbitration were again under discussion. The area of the territory in dispute was only 23,306 sq. km., and only 18,000 ac. were in 1921 under cultivation. The pop. numbered no more than 37,000, and the trade and industry were almost negligible. Nor were any ethnical, linguistic or religious considerations involved, the inhabitants, whether Chilean or Peruvian, being of the same race, speaking the same language and professing the same faith.

TACTICS¹ (see 26 347*)—While personal reminiscences of the Great War had up to 1921 appeared in plenty, and in many languages, it is remarkable that so far no comprehensive and scientific study of its abiding tactical lessons had been published. Diarists and biographers there had been, also not a few training-manuals and text-books, but the world was still awaiting the Clausewitz or Henderson who would show it how military science developed from 1914 to 1918 in the minds of great leaders, how the world struggle differed from anything and everything that preceded it, and how it was finally lost and won. This is the task which will eventually confront the true biographer of Marshal Foch, the greatest soldier figure of the war, when it becomes possible to follow his innermost thoughts during the progress of the conflict. The future historian will have to show how principles and theories which had been developed during a lifetime of profound study were abandoned, modified or confirmed as the result of experience of modern war, contact with the military chiefs of Allied nations and bitter contest with the best military brains Germany and Austria could produce. When some skilled military writer shall have interpreted Marshal Foch as G. F. R. Henderson interpreted Lee and Stonewall Jackson, it may be possible not only to understand the Allied victory but perhaps even to penetrate into the future and to realize some of the simpler problems which war on the great scale has in store. That is the best the military historian can hope to do—so to present the picture of the past as to throw

¹ This article may be considered also as supplementing, for the World War, the article *STRATEGY* (25 986).

* These figures indicate the volume and page number of the previous article.

some light upon the obscurity of the future. Always we are left groping our way through what is at the best semi-darkness, but any ray of light is helpful. It is in this spirit and with full consciousness of the difficulties and dangers which lie ahead that the present writer attempts here the task of reviewing the practical developments of the decade 1910-20 and of presenting them in a form which in 1921-2 might already be out of date.

I.—TACTICS IN THE WORLD WAR

Tactics and Strategy.—First it may be as well to inquire exactly what is meant by tactics, and whether the division between strategy and tactics is left as clear as it was before the World War introduced the new feature of continuous lines offering no flanks for attack, and ceaseless fighting which, from day to day and month to month, varied only in intensity.

Let us ask two questions (a) Can grand or combined tactics still be defined as the sphere of the higher commander on the day of battle? and (b) if so, can we accept the corollary that all the fighting on the western front from 1915 until 1918 was tactical and outside the sphere of strategy? All days were battle days, but does this mean that the problems which the commanders of the British, French and Italian armies in the field were called upon to solve were essentially tactical in their nature? The definition may require some modification, but to the second question the answer is distinctly "Yes." They were vast problems involving all sorts of considerations, but they were essentially tactical. Questions of strategy, so far as Britain was concerned, were dealt with in London, or in conference with her Allies in Paris, Rome or elsewhere. It was in these places and not in the field that great decisions were formed as to the despatch of troops to the various theatres of war, the formation of new forces, and the wisdom, or the reverse, of embarking upon fresh undertakings. Behind them all were the equally anxious problems of finance and allotment of man-power. In modern wars, Army, Navy (in which is included the Merchant Marine) and Munitions are only three departments of the nation, each puts forward its rival claims, which can only be judged by the Government in consultation with the technical advisers. And so it is that, as war absorbs into itself more and more of a nation's energies and resources, the Government with the prime minister at its head must accept responsibility for strategy in the highest possible sense of the word. In no sense, however, can the Government be held to be responsible for tactics, which are the exclusive sphere of the military commanders. The Government, in consultation with their technical advisers, allot troops, soldiers alone command them. Whether that command, in its turn, gives scope for strategy, as in Palestine, or only for grand tactics, as on the western front, depends upon the number of men available in proportion to the size of the theatre of war, upon the railway and road development of the theatre of operations, and upon many other considerations.

Strategy, now as always, is the art of bringing the enemy to battle on terms which are disadvantageous to him, *grand tactics* are the methods employed for his destruction by a force of all arms. Before the war, when aviation was still in its infancy, the term "all arms" included as a rule no more than infantry, artillery and cavalry. Even the engineers were rarely considered as having any direct influence upon the result of a battle. All this is changed, and to the four arms there must now be added, without any doubt, aeroplanes and tanks, and it is a matter for the gravest consideration whether in future wars the chemist will not occupy as important a position as he now does in peace. Machine-guns are purposely excluded here, not because their importance is underrated, but merely in the hope of avoiding unnecessary complication and because they may be included in the wide term of infantry, which also covers such accessories as bombs and rifle grenades.

The sphere of the higher commander in battle is therefore by so much enlarged in that he must know how to utilize and combine far more weapons than were at his disposal in earlier wars, and the demands made upon him are in the same degree heavier and more complex. And so through all the long chain

of command, from "the Chief" at G.H.Q. to the platoon commander in the foremost trench. It has been amply proved that, more than ever, no arm of the service is complete in itself; each requires in a greater or less degree the assistance of others in order to win even a small success. The smallest raid into a German trench needed hours, almost days, of careful preparation. Night patrols and aeroplane photographs for reconnaissance; artillery and trench mortars to destroy the enemy's wire, if the ground won is to be held; engineers must help to make it good, and even if it is not to be held the engineers must be called upon to destroy with explosives enemy machine-gun emplacements or other defences. Then, according to the object of the raid and the intentions of the commander, arrangements must be made for the withdrawal or reinforcement of the raiding party, all of which require most thorough and careful forethought. Much of the detailed preparation for a minor operation of this kind will fall upon company and platoon commanders, and when it is remembered that in war platoons may be, and often are, commanded by junior non-commissioned officers, it is seen that, just as responsibility for the success of higher strategy must depend upon the wisdom of the prime minister and the Government, so responsibility for tactical success extends to the last link in the chain of military command.

War has become national in a sense in which it never was before, and it is a sad reflection that, after twenty centuries of Christianity, its study is more important than ever. Owing to the insular position of Great Britain, its dense population and consequent dependence upon overseas trade, it, more than any other country, is dependent upon success in war. No country in the world could so ill support defeat, yet in no country is the study of war so much neglected. There has recently been a most praiseworthy effort to train the British soldier in the arts of peace, it might be well if similar efforts could be made to fit the civil population in all classes of society for the vital responsibilities of war. The response to Lord Kitchener's appeal in 1914-5 proved beyond doubt the essential soundness of the national spirit, but the story of a hundred battles proves that spirit without professional knowledge and skill is desperately expensive in life.

Hence it is that, just as our conception of war has become national and the need of study more general and less strictly professional, so our definition must be less restricted. We prefer to regard tactics, even "combined tactics," simply as the art of commanding troops in action, without any limitation as to the number of troops employed or the status of the commander. Indeed, it is perhaps easier, in considering the fighting in France and Belgium, to exclude the rôle of the commander-in-chief than that of many of his junior subordinates. Nevertheless, for the purpose of this article, we shall be concerned entirely with the sphere of the larger formations, with organization and equipment, with the effect of inventions upon attack and defence, and with the changes and developments in tactics since Russia and Japan fought themselves to a standstill in the plains and highlands of Manchuria.

Communications.—Now, these changes have been brought about by exactly the causes which have produced the whole evolution of tactics during the last two thousand years, namely, improvement in weapons and communications—that is, in conveying ever more men to the field of battle and in furnishing them with ever more efficient means of killing when they get there. For, after all, the object of tactics is to kill, if possible without being killed, but in any case to kill. For the first time in history these developments enabled armies during the World War to be placed and maintained in positions which offered no flanks for attack and therefore afforded no scope for strategy or for manœuvre. Increase of population was a contributory cause, but primarily the "continuous lines" extending from sea to sea were rendered possible only by the development of railway and road communications, and by firearms of marvellous range, rapidity and precision. It was these features, existing so far only in Europe, and attaining their fullest influence only in western Europe, which differentiated the World War from everything

which preceded it. Something of the same kind was seen during the Russo-Japanese War, when great mountain ranges made movement far from the railway extremely difficult, with the result that, broadly speaking, neither Oyama nor Kuropatkin had room for manoeuvre, and tactically the war resolved itself into a series of frontal assaults on a defended defile. So it was that, from 1914 to 1918, commanders on the western European front had no opportunity for crushing strokes and striking victories like Austerlitz, Rossbach or Salamanca. Their genius had to show itself rather in the skill and ingenuity with which they made use of the resources placed at their disposal by modern science, than in rapidity of movement and dashing leadership. More than ever war has become "an art served by many sciences," but in so doing it has lost much of its romance. It was only as they moved eastward out of Europe to Palestine and Mesopotamia, where restricted railway communications and scanty populations made it necessary to operate with comparatively small forces in big countries, that the British commanders found themselves working under conditions which previous experience had made familiar to them. Before 1914 instances of the tactical use of railways could be numbered on the fingers of one hand, the arrival of the ever-famous Stonewall brigade on the battlefield of Bull Run, the dramatic appearance of Lambton's naval brigade at Ladysmith on the morning of Oct. 30 1899 at a critical moment in the action of Lombard's Kop, and one or two other examples complete the tale of occasions when railways can fairly be said to have had a direct influence upon a tactical decision.

All this is now changed. Broad-gauge and light-gauge lines are now a necessary and ever-increasing part of the mysterious machinery of battle; and it is they, together with the complementary service of road transport, that have made it possible to mobilize the entire manhood—almost the whole adult population—of a nation, and to maintain in the field armies numbering several millions of men. These armies in their turn claim the services of every industry and every factory to such an extent that in time of war the term "civilian population" is merely misleading, and undefended towns and ordinary merchant vessels become legitimate objects of attack. Thus it is that the new feature of "continuous lines" has been introduced into civilized war, and frontal attacks have become inevitable.

Obstacles: Wire.—Here, however, we must stop to consider another new factor which has resulted directly from the extended use of railway communications and the "nationalization" of war. This is the use of obstacles, more particularly of wire. For several years before 1914 it had been amply evident to every student of the great military problem of Europe that, so soon as the German armies were mobilized and received the order to march, every road between the Dutch frontier and the mountains of Switzerland would be filled to overflowing with advancing troops. There was, be it noted, no doubt whatever among competent soldiers that Germany would not hesitate to violate the neutrality of Belgium; indeed, the very size of her armies, as well as her declared principle of envelopment, made it certain that she would do so, even had the fortifications of the eastern frontier of France not barred the way from Alsace and Lorraine to Paris. To this extent, therefore, "continuous lines" had been foreseen, but it was generally considered that they would exist only during the opening phase.

The present writer can recall very clearly an interesting argument between a very distinguished senior officer and two of his subordinates which took place early in 1914. The senior officer maintained that he found it impossible to visualize a collision along a front of something like 140 miles. The two subordinates maintained that this gigantic battle must be the result of the numbers which would certainly be mobilized, clearly it could not last very long before it broke up into groups of armies operating semi-independently, but, taking Mukden as something of a guide, they expected to see the first, and perhaps the decisive, battle rage from Belfort to the neighbourhood of Namur for perhaps three weeks. "Well," was the senior officer's final remark, "I'll give you three weeks, but not a day longer," and

with that the juniors departed content. Some things, it will be seen, turned out as anticipated; but many, especially the rapidity of the Allied retreat, turned out very differently. On the one hand, the German movement through Belgium was too quick and too successful to allow the Allied armies to make the expected stand; on the other hand, the continuous lines were never broken, and after three months of moving warfare the *siege of Germany* began. Once started, it lasted, not for three weeks, but for four whole years—a phenomenon which was due to field fortifications and, more than anything else, to wire.

It is a remarkable fact that in all the tactical exercises, staff rides and other instructional devices in which soldiers were accustomed to indulge before the war, the problem of field fortification was but lightly considered. This is true of all countries, and it is quite wrong to believe that Germany, as has been held in too many quarters, showed any greater prescience than her enemies. The reasons are simple: first, it was not possible to test the efficacy of trenches, dug-outs, barbed-wire entanglements or "pill-boxes" under manoeuvre conditions, when time was short and compensation a grave consideration; secondly, it was generally agreed that fortified positions limited the offensive power of the defending garrison and could themselves be easily avoided or turned. This was the teaching of the South African and all previous campaigns, and even Manchuria gave but little indication of what war was to be like in the highly industrialized areas of western Europe. Thus it was that, at the end of the first battle of Ypres, in the middle of November 1914, the British, French and German armies found themselves confronted with entirely novel tactical conditions which demanded entirely new tactical treatment; and to-day new tactics involve not only the training of troops but also the application of mechanical device. In 1914 the new conditions were those of "continuous lines," for which the solution was eventually found, but only through a weary process of "trial and error," in the course of which the ultimate victors came perilously near to exhaustion.

It is not proposed here to discuss the various methods which were adopted with a view to avoiding the central problem and seeking a decision in other theatres of war, for they have nothing to do with tactics. It is, however, permissible to refer to the effect of operations in different theatres of war upon the tactical evolution in the armies of the Allies and of the Central Powers.

Interior Lines.—Put quite briefly, it would appear to be this—that, as a result of their central position and possession of interior lines facilitating the rapid transfer of troops from one theatre of operations to another, the German commanders were not so free to concentrate their attention upon the demands of local conditions as were the French and especially the British. The theatres of Mesopotamia, Gallipoli and later of Salonika and Palestine were so remote from France and from each other that it was less difficult to allot to each the necessary proportion of the different arms, and to give to each the distinct training and equipment essential for its efficiency, than it was for Germany, whose troops and commanders were constantly on the move from one theatre to another. Hence it was that, while Germany was inclined, or compelled, to compromise, the Allies opposed to her were able to specialize, with the result that, with one notable exception, in every theatre the initiative and the lead in tactical development were with them. That notable exception was the not very noble or praiseworthy one of the use of gas. In the true realm of tactics it may fairly be said that, from the end of 1914 until March 1918, when Ludendorff had for the first time been able to devote his individual attention to the problems of the western front, the lead in tactical evolution was always with the Entente armies.

Changes in Organization.—To return to the deadlock in the West, it became clear towards the end of 1914 and beginning of 1915 that the problem of field fortification could not be solved by the methods of 1870, S. Africa or Manchuria. It was not that principles were changed and theories at fault. The power of modern rifle fire had been amply demonstrated, especially by the British Expeditionary Force, whose trust in their weapons had been more than justified; the French seventy-

five, the British long-range field gun (for as such the 60-pounder must be regarded), and indeed the German heavy howitzers had done all that had been expected of them, but one and all failed to compete successfully with the new factor. Infantry, even with the best available artillery support, could not be expected to assault with success the hostile lines, which were daily becoming stronger, and cavalry, which had been invaluable during the retreat of Aug and the early days of Sept 1914, as well as in the subsequent advance, could find no scope when Nov. and Dec. came. No vulnerable flank was offered, nor was there the slightest opportunity for those daring raids against the hostile communications which have sometimes offered such dangerous attraction to the cavalry leader. The conditions were indeed the exact opposite of those in S. Africa during 1899-1902. Similarly, the German army had been able to prove that the theory of tactical envelopment was the inevitable corollary of machine-guns and quick-firing artillery, for frontal attack was far too costly, and Joffre and French and their lieutenants had once more proved to the world that counter-attack was the soul of successful defence. It was not that the principles or theories were wrong; so far as they went they were correct enough, but the trouble was that they did not carry sufficiently far. Their basis was manœuvre, and suddenly it was found that manœuvre was no longer possible, but that it had been displaced by the tedious processes of siege warfare. Infantry was still the conquering arm, but was now less dependent upon cavalry and even more dependent upon engineers and artillery, while the Air Force was rapidly acquiring an importance which, though foreseen, had in peace always been put aside by considerations of expense. It was at this stage, too, that the bomb first made its reappearance as an infantry weapon, and its use increased to such an extent that, towards the end of the battle of the Somme, in the autumn of 1916, it threatened to supersede the rifle. Many new auxiliary services grew up, many new weapons were invented, and leading men in every branch of science devoted their great talents to the destructive art of war.

Yet amidst so much which was new the great central problem of war remained unchanged, for it was, as it always has been, the destruction of the enemy's field army. In the new conditions which had arisen this meant great innovations in army organization. The cry was for more technical troops of all kinds. A third field company (engineers) and a pioneer battalion were added to each British division, the signal service was greatly extended, and, above all, the demand for more and heavier artillery was urgent. Every month, almost every week, new needs were discovered and fresh demands from the armies in the field were reaching the British authorities at home, who were already more than fully employed in equipping Territorial divisions and in raising new armies. Put quite broadly, however, the problem of the capture of the German fortified lines, which could not be turned, was one of improved material and improved cooperation between artillery and infantry, each with the attendant services necessary to efficiency. That is the main thesis to which it will be necessary to return again and again.

Artillery and Infantry Cooperation.—At this point it will be as well to look backward and to trace very briefly the history of the evolution of artillery and infantry cooperation for the previous twenty years or so. It is the story of the contest between artillery and field fortification, which in some respects resembles that between the gun and armour at sea, or between ships and forts. It is, in fact, the old contest between attack and defence. For many years before the S. African War it was an accepted axiom of combined tactics that any attack by infantry must be preceded by an artillery bombardment, of which the principal purpose was partly to overcome the enemy's artillery and partly to shake the *moral* of his infantry. Accustomed as we have become during the last few years to think of guns at least in hundreds, it seems strange to turn to the official account of the battle of Magersfontein (1899) and to read that at 4.30 p.m., on the day preceding the attack which was to take place at dawn, the British force opened fire with one 4.7 gun, one battery of howitzers and three of field artillery, which "shelled Magers-

fontein Hill for two hours. . . . Though his guns had provoked no reply from the Boer, Lord Methuen felt confident that they had not only inflicted loss, but had produced considerable moral effect upon the Boer commander. This, however, was not the case. The fire had but one important result, that of warning the enemy that an attack was imminent." The fact was that in those days military science overestimated the powers of a few guns and underestimated those of hastily constructed entrenchments, which were then in their infancy and almost an unconsidered feature of war. Again and again the same thing occurred, but so difficult is it to learn from any experience but one's own that we find the Japanese army making exactly the same mistake some four years later. Then, at the action of Ta-shih-chiao, the Japanese, with a vastly stronger artillery than the British had possessed at Magersfontein, bombarded the Russian right for several hours. So heavy was the fire on this occasion that General Stakelberg declined to occupy his trenches, and reported to his senior officer that, should he be forced to do so in order to repel an infantry attack, he would certainly suffer very heavy loss. But no infantry attack developed, Stakelberg's troops remained under cover, and the losses inflicted by the bombardment were almost negligible. From these and many similar experiences the theory was deduced that, in order to get results from the fire of the guns, the artillery bombardment must be accompanied by an infantry attack. To cooperate successfully, the action of the two arms must be simultaneous instead of successive, for only in this way could the enemy be compelled to man his defences, to show himself above his parapets, and to expose himself to shrapnel fire. In the words of the French regulations of 1913: "Artillery no longer *prepares* the infantry attack, but *supports* it." The old term, "artillery preparation," belonged to a dead language.

Such, in a few words, was the generally accepted theory of infantry and artillery cooperation at the beginning of the World War, and during the earlier stages it proved to be remarkably correct. It was not until the field armies found themselves brought up short by deep trenches protected by wire entanglements, furnished with strong revetment, and strengthened by dug-outs, that the experts discovered that, curiously enough, new conditions must be met by old methods, and the discarded, not to say discredited, "artillery preparation" was revived.

Up to this point, too, it may be fairly claimed that the actual artillery material with which the various armies took the field in the autumn of 1914 had stood the test well, although naturally subjected to the restrictions on ground of expense which are inevitable in times of peace. Each artillery, English, French and German, had, however, developed on somewhat different lines, corresponding to the mentality of the different nations, their theories of battle fighting and the amount of money available for each experiment. Each of the three armies had a mobile field gun, England the 18-pounder, France her famous 75-millimetre and Germany the 77. France, thinking always of rapid movement either in retreat or advance, and always refusing to consider the possibility of standing on the defensive, had concentrated on the light, rapid-firing and very accurate field gun, with an organization on a divisional basis. England also believed in the divisional organization, but in addition to the 18-pdr. she had the 4.5-in. howitzer for high-angle fire, which had been found so necessary in S. Africa, and the 60-pdr., whose long range, commanding the roads and often forcing premature deployment of the German infantry, was invaluable during the retreat. The German army alone possessed heavy howitzers and high explosive, no doubt because the general staff always considered the possibility of being forced to engage permanent fortifications on the French and Belgian frontiers, but it was weak exactly in those points upon which the French and English had specialized. The 77-mm. was inferior as a field gun both to the 75-mm. and to the 18-pdr., it possessed nothing corresponding to the 4.5-in. howitzer; and its heavy artillery, while possessing great shell power, was lacking in range. Thus it came about that, when expense was no longer a ruling factor, each army began to borrow ideas from the other and to adopt material

suitable to the wearisome ordeal of trench warfare. Thus, too, Europe stumbled into that war of material, of ever stronger material of defence and ever stronger material of attack, which was to last until the autumn of 1918. It was under these conditions that the German army, which was to have been back in its own homes "by the fall of the leaf," found itself pinned to French and Belgian soil, and that the war, which at the outset, as was believed by most of the leading authorities in England, political, military and financial, could not last more than six months, dragged out its devastating existence for more than four long years. One man among them alone ventured at that early stage to lay his plans for a long war, Lord Kitchener.

Offensive or Defensive?—It was a depressing situation for the professional soldier of England, France or Germany to find himself in. No matter to which of the three armies he happened to belong, he had been trained from youth in a war of movement, of stroke and counter-stroke, and of rapid decision. The more he knew of the history of his profession, the more deeply he had studied the campaigns of the great captains, the firmer was his belief in the power of the offensive and the "will to conquer." There was much searching of heart, especially among those who had seen the German masses beaten back time after time by the attenuated lines of the British Expeditionary Force in the first battle of Ypres. If the rifle alone could do so much, how was it possible to overcome strong defences heavily protected with barbed wire and bristling with machine-guns? Had modern developments changed not only the methods of warfare but the very basic principles themselves? Had, in fact, the defence become stronger than the attack?

There were those who thought that a decision, since there must be one somehow, must be sought elsewhere than in France or Flanders, and there arose the controversy between "Easterners" and "Westerners," which lasted as long as the war itself. But that great question carries us into the region of strategy. Clearly no commander could be content to sit still and avoid a decision on his own front, at least without direct orders from the supreme authorities. Nevertheless, the same causes which gave birth to the desire to "find a flank" elsewhere than in France produced even on the western front two schools of thought, which were christened by the French, with their wonderful gift for discovering appropriate labels, the "usuristes" and the "trouistes." The former, as their name implies, held that nothing could be gained by hurling infantry, however well supported, against the German lines. In support of this view they were able to point to the desperate losses which were incurred in the fruitless fighting of the early part of 1915, and to the opinion of a captured German officer who, when asked when and how he thought the war would end, was said to have replied: "In about six months' time, and about fifty metres from where we now are." A war of attrition, and victory through exhaustion, or by somebody else's efforts in some other field, were the tenets of the "usuristes." These theories found no appreciable support in the British army, nor in the British troops from overseas or in the Dominions whence they came. The war of attrition was rightly regarded by them as a dangerous "will-o'-the-wisp" which was bound to lead to disaster, for it meant the abandonment of that "will to conquer" which has always been the greatest asset of victorious leaders, and depended for success upon the collapse of the enemy's *moral* rather than upon the triumph of their own. The arguments of the "usuristes" could not be disproved. They could be met by faith alone; but faith was not lacking, and the names which will always be held in the highest honour in every country are those of leaders, whether political or military, who never lost their belief in the power of the offensive and refused to be tempted into the broad and easy path of the "usuristes."

The "trouistes" had their way, and in the end they compelled victory. The principal article of their belief was a firm conviction that morally the defensive is the weaker role, and that the path to victory must always lie through a wisely and resolutely conducted offensive. Put shortly, and in axiomatic form, "there is no defence which cannot be broken." The

formula was simple, but the proof was only found after three more years of trial and error.

Since the very earliest days of the war the cry in every army had been for more and heavier artillery, with more and heavier shells, and the fighting of the earlier part of 1915 merely emphasized the same need. By Sept. 1915 the French and British armies, no less than the German, had been provided upon a scale never before dreamt of, but yet far below that which was to be reached before the war was over. Side by side with this vast expansion went the increase of the signal corps, for without cooperation between the arms it was clearly useless to expect the full value from either. Before the war, both in France and England, this subject of co-operation had received great attention. It formed the subject of countless essays, lectures and articles in technical magazines. All that was lacking was practical application and testing under service conditions. Probably the Signal Service which took the field with the British Expeditionary Force excelled both the French and the German, but it depended largely upon despatch-riders, admirable in a war of movement but of less use on a modern battle field. In the words of a French writer "Il eût mieux valu quelques harangues de moins sur la liaison, sur l'union des coeurs d'artilleurs et de fantassins, et quelques kilomètres de plus de fil téléphonique." But telephone wire costs money, and its absence is just one of those difficulties with which every army must expect to be faced at the beginning of a great war. By Sept. 1915, however, the Signal Service, the link between infantry and artillery, was well equipped; but, in the absence of practical experience, its possibilities and limitations were not yet realized. In this direction, as in many others, much was still to be learnt.

First Great French Attack—Material equipment was provided lavishly and the first of the great attempts to burst through the enemy's lines was eventually fixed for Sept. 25 1915. At that date much of the British army was still new and inexperienced, so the main attack was delivered entirely by the French in the Champagne country. Farther to the north subsidiary attacks were launched both by the French and the British, but with them we are not concerned. Already the old formula: "The artillery does not prepare the attack, but supports it," had been so far abandoned that three days were devoted to the destruction of enemy's defences by guns of every calibre, and these had themselves been preceded by several days of counter-battery work; thus was seen the revival of the old discredited "artillery duel," which cannot fail to interest the eventual historian of tactical evolution.

It is clear that an attack which is thus prepared has one grave weakness. The exact time, and even the day, of the infantry assault may be concealed from the enemy unless he is sufficiently fortunate to capture a prisoner who knows and can be persuaded to part with the secret, but there is nothing of the rapid march followed by the speedy onslaught and crushing blow of a Lee or a Stonewall Jackson. On the contrary, the attack is not only faced by astonishingly strong defences but is at the same time deprived of what is perhaps its principal weapon—surprise. Some efforts were, of course, made to conceal the exact area selected for the main attack by carrying out similar bombardments on other parts of the front, but the vast amount of ammunition necessary for a real destruction of wire defences and dug-outs rendered it impossible to carry out a thorough preparation at more than one or two points. Thus it came about that the element of surprise was lacking, and the attack was to this extent weakened. Nevertheless in the initial stages it was almost completely successful. The hostile front was broken on a front of 15 miles, and some 20,000 prisoners were taken, together with about 100 guns.

Great hopes were raised momentarily, not only on the fighting front but in London and in Paris. But these hopes were sadly dashed, for it was quickly discovered that, after all, the real difficulty for the assaulting troops was not the capture of the enemy's organized first-line defences, formidable and almost impregnable though they had hitherto appeared to be, but the exploitation of success. So soon as the great attack had been

five, the British long-range field gun (for as such the 60-pounder must be regarded), and indeed the German heavy howitzers had done all that had been expected of them, but one and all failed to compete successfully with the new factor. Infantry, even with the best available artillery support, could not be expected to assault with success the hostile lines, which were daily becoming stronger, and cavalry, which had been invaluable during the retreat of Aug and the early days of Sept 1914, as well as in the subsequent advance, could find no scope when Nov. and Dec. came. No vulnerable flank was offered, nor was there the slightest opportunity for those daring raids against the hostile communications which have sometimes offered such dangerous attraction to the cavalry leader. The conditions were indeed the exact opposite of those in S. Africa during 1899-1902. Similarly, the German army had been able to prove that the theory of tactical envelopment was the inevitable corollary of machine-guns and quick-firing artillery, for frontal attack was far too costly, and Joffre and French and their lieutenants had once more proved to the world that counter-attack was the soul of successful defence. It was not that the principles or theories were wrong; so far as they went they were correct enough, but the trouble was that they did not carry sufficiently far. Their basis was manœuvre, and suddenly it was found that manœuvre was no longer possible, but that it had been displaced by the tedious processes of siege warfare. Infantry was still the conquering arm, but was now less dependent upon cavalry and even more dependent upon engineers and artillery, while the Air Force was rapidly acquiring an importance which, though foreseen, had in peace always been put aside by considerations of expense. It was at this stage, too, that the bomb first made its reappearance as an infantry weapon, and its use increased to such an extent that, towards the end of the battle of the Somme, in the autumn of 1916, it threatened to supersede the rifle. Many new auxiliary services grew up, many new weapons were invented, and leading men in every branch of science devoted their great talents to the destructive art of war.

Yet amidst so much which was new the great central problem of war remained unchanged, for it was, as it always has been, the destruction of the enemy's field army. In the new conditions which had arisen this meant great innovations in army organization. The cry was for more technical troops of all kinds. A third field company (engineers) and a pioneer battalion were added to each British division, the signal service was greatly extended, and, above all, the demand for more and heavier artillery was urgent. Every month, almost every week, new needs were discovered and fresh demands from the armies in the field were reaching the British authorities at home, who were already more than fully employed in equipping Territorial divisions and in raising new armies. Put quite broadly, however, the problem of the capture of the German fortified lines, which could not be turned, was one of improved material and improved cooperation between artillery and infantry, each with the attendant services necessary to efficiency. That is the main thesis to which it will be necessary to return again and again.

Artillery and Infantry Cooperation.—At this point it will be as well to look backward and to trace very briefly the history of the evolution of artillery and infantry cooperation for the previous twenty years or so. It is the story of the contest between artillery and field fortification, which in some respects resembles that between the gun and armour at sea, or between ships and forts. It is, in fact, the old contest between attack and defence. For many years before the S. African War it was an accepted axiom of combined tactics that any attack by infantry must be preceded by an artillery bombardment, of which the principal purpose was partly to overcome the enemy's artillery and partly to shake the *moral* of his infantry. Accustomed as we have become during the last few years to think of guns at least in hundreds, it seems strange to turn to the official account of the battle of Magersfontein (1899) and to read that at 4.30 p.m., on the day preceding the attack which was to take place at dawn, the British force opened fire with one 4.7 gun, one battery of howitzers and three of field artillery, which "shelled Magers-

fontein Hill for two hours. . . . Though his guns had provoked no reply from the Boer, Lord Methuen felt confident that they had not only inflicted loss, but had produced considerable moral effect upon the Boer commander. This, however, was not the case. The fire had but one important result, that of warning the enemy that an attack was imminent." The fact was that in those days military science overestimated the powers of a few guns and underestimated those of hastily constructed entrenchments, which were then in their infancy and almost an unconsidered feature of war. Again and again the same thing occurred, but so difficult is it to learn from any experience but one's own that we find the Japanese army making exactly the same mistake some four years later. Then, at the action of Ta-shih-chiao, the Japanese, with a vastly stronger artillery than the British had possessed at Magersfontein, bombarded the Russian right for several hours. So heavy was the fire on this occasion that General Stakelberg declined to occupy his trenches, and reported to his senior officer that, should he be forced to do so in order to repel an infantry attack, he would certainly suffer very heavy loss. But no infantry attack developed, Stakelberg's troops remained under cover, and the losses inflicted by the bombardment were almost negligible. From these and many similar experiences the theory was deduced that, in order to get results from the fire of the guns, the artillery bombardment must be accompanied by an infantry attack. To cooperate successfully, the action of the two arms must be simultaneous instead of successive, for only in this way could the enemy be compelled to man his defences, to show himself above his parapets, and to expose himself to shrapnel fire. In the words of the French regulations of 1913: "Artillery no longer *prepares* the infantry attack, but *supports* it." The old term, "artillery preparation," belonged to a dead language.

Such, in a few words, was the generally accepted theory of infantry and artillery cooperation at the beginning of the World War, and during the earlier stages it proved to be remarkably correct. It was not until the field armies found themselves brought up short by deep trenches protected by wire entanglements, furnished with strong revetment, and strengthened by dug-outs, that the experts discovered that, curiously enough, new conditions must be met by old methods, and the discarded, not to say discredited, "artillery preparation" was revived.

Up to this point, too, it may be fairly claimed that the actual artillery material with which the various armies took the field in the autumn of 1914 had stood the test well, although naturally subjected to the restrictions on ground of expense which are inevitable in times of peace. Each artillery, English, French and German, had, however, developed on somewhat different lines, corresponding to the mentality of the different nations, their theories of battle fighting and the amount of money available for each experiment. Each of the three armies had a mobile field gun, England the 18-pounder, France her famous 75-millimetre and Germany the 77. France, thinking always of rapid movement either in retreat or advance, and always refusing to consider the possibility of standing on the defensive, had concentrated on the light, rapid-firing and very accurate field gun, with an organization on a divisional basis. England also believed in the divisional organization, but in addition to the 18-pdr. she had the 4.5-in. howitzer for high-angle fire, which had been found so necessary in S. Africa, and the 60-pdr., whose long range, commanding the roads and often forcing premature deployment of the German infantry, was invaluable during the retreat. The German army alone possessed heavy howitzers and high explosive, no doubt because the general staff always considered the possibility of being forced to engage permanent fortifications on the French and Belgian frontiers, but it was weak exactly in those points upon which the French and English had specialized. The 77-mm. was inferior as a field gun both to the 75-mm. and to the 18-pdr., it possessed nothing corresponding to the 4.5-in. howitzer; and its heavy artillery, while possessing great shell power, was lacking in range. Thus it came about that, when expense was no longer a ruling factor, each army began to borrow ideas from the other and to adopt material

were unavoidable, but it was found far safer for infantry to run the risk of an occasional short burst than to let the barrage run away from them, leaving them exposed to enemy machine-guns.

Two other points in connexion with the Somme battle are especially worth noting. First, several attempts were made to operate on a really large scale by night, and on one occasion at least considerable success was won. Secondly, tanks made their first appearance, an event of real historic importance.

Nevertheless it must be admitted that 1916 brought the Allies little if any nearer to the longed-for "break-through" than had 1915, and largely for the same reasons. Again it was evident that prolonged bombardment was the enemy of surprise. Again it had been found that the first system of defence was far less difficult to deal with than were the less well-organized and comparatively ill-defined lines in rear. In addition it was discovered that the shell-torn ground opposed a formidable obstacle to the movements of the attacking infantry, while every hole was a ready-made emplacement for a German machine gun.¹ Great things had indeed been achieved both by the British and the French armies but the enemy was not crushed, and after months of fighting on an unprecedented scale he still preserved an unbroken front from the English Channel to the Swiss mountains. This time the explanation was held to be that, after all, the system of limited objectives was wrong, for the delay necessitated by the methodic preparation for each successive attack merely permitted the enemy to recover from the previous reverse, to bring up reserves of infantry and artillery, and to organize a fresh defence. Thus at each stage of the battle the defence grew stronger, and the attack weakened until it at last died from exhaustion. From this premise it followed that if real success was to be won the artillery preparation must be heavier than ever but in greater depth, and the infantry must pass through all the successive lines of defence in one irresistible rush. Such was the teaching of the French official instructions of Dec 1916 which prepared the ground for Gen. Nivelle's disastrous attack in April 1917.

Lessons of 1917.—Unlike its predecessors, the campaign of 1917 was singularly unfruitful in tactical ideas. Partly owing to insufficient preparation, partly to over-confidence and partly to want of secrecy—for it was commonly reported that every flower-seller in Paris knew exactly what was intended—the great French offensive by the IV., V. and VI. Armies met with a severe reverse. The subsidiary attack by the British I., III. and V. Armies was more successful, but again resistance was found more difficult to overcome as the attack progressed, and the operations were finally abandoned when it became evident that the main attack, from which so much had been hoped and expected, could not attain its object.

The principal scene of operations then became the Ypres area. First the capture of the Messines ridge, and then the prolonged attack, in appalling weather and on a narrow front, against the Passchendaele ridge. As had happened on every previous occasion, the first system of enemy defences fell easily enough,² but difficulties increased just when, theoretically, they should have been most easy to overcome. The artillery "preparation," on a scale far greater even than in the Arras battle of April, did its work only too well, for, coupled with the heavy rains, it converted a naturally swampy country into a pock-marked morass, intensifying in a high degree the troubles of the infantry, and greatly curtailing the usefulness of the tanks, which were by this time an important new arm of offense. During this period, too, the use of gas, especially the newly discovered "mustard" variety, became more persistent and more general than ever before. Masks were worn for hours on end, and so impregnated did the soil become that many men suffered merely

¹ In addition the British armies in particular had to overcome almost incredible difficulties in keeping up the requisite supplies of ammunition and food over a country which was almost devoid of roads. It was indeed found necessary to institute a regular road department of the transportation directorate.

² It should also be noted that the perfection (coupled with ample supply) of instantaneous fuzes now made the destruction of wire defences a far simpler affair than it had been before.

from sitting or lying down to rest. Never has any army fought under greater disadvantages than did the British during the autumn of 1917, yet, even if it did not do what was hoped from it, it is only necessary to read Ludendorff's account to realize how heavy was the strain upon the German resources. Moreover, under the leadership of Hindenburg and Ludendorff, the defensive strategy and tactics of the German army had been radically overhauled during the winter of 1916-7, and the *moral* of the troops had been wonderfully improved. Indeed, the army which held the French on the Aisne, the British at Arras and the combined Allies round Ypres was altogether different in spirit from that which had been hunted back to the Hindenburg line during the previous winter. Even the air service responded to the new spirit, and the Entente troops no longer enjoyed the immunity from bomb attacks which had been theirs throughout 1916, far from it. Such was the effect of the masterful and trusted leadership which now had control of the German army.

Tactically, the principal change brought about by the new régime was a greater elasticity in defence, which aimed at affording as ill-defined a target as possible to the attacking artillery and the vaguest possible objective to the assaulting waves of infantry. In reserve were held certain battalions whose duty it was to advance to the counter-attack as soon as it was known that an attack had been launched, and thus it came about that more than once infantry which was in process of organization and consolidation after a successful attack found itself thrown upon the defensive and perhaps forced back from a position which had been dearly won. Special aeroplanes were detailed to look out for these counter-movements, and special batteries to deal with them, sometimes by putting down a defensive barrage of gas, and from these small beginnings grew up that war of movement which gradually reasserted itself and increased in intensity until at last the war was lost and won. More and more as the great attacks, whether French, British or combined, failed to win a decisive result, it was realized that in some way or another the element of surprise must be reintroduced, for without it the offensive was deprived of almost half its power. But the question was, How could the enemy defences be overcome without the preliminary bombardment which inevitably "gave away" the assailant's intended plans? The solution of the problem was at last found in the use of tanks, and at the battle of Cambrai tanks came into their own.³ Massed secretly by night conveniently near the objective, and advancing when the time came under cover of an artillery barrage, but over ground which had not been rendered impassable by tons of heavy shell, the tanks effected a complete surprise, passed line upon line of defences, and enabled supporting infantry to occupy an important area of ground with but little loss. So severe had been the drain upon the German reserves during the Ypres fighting that for some twenty-four hours the British troops were within an ace of really effecting a break-through, and Ludendorff has himself said that if they had been able to push on a little farther they might have broken in upon his communications and so have scored a considerable strategical success. But the drain upon the British reserves had been no less heavy than upon the German, and the necessary weight to turn a tactical victory into a strategical success was just lacking. In the end Ludendorff was able to mass troops for a counter-attack, and some of the ground which had been lost was re-won; but for the Allies by far the most important result of the Cambrai fighting was that the "trouistes" had been able to justify the faith which was in them and to show that there was a way leading to decisive victory—namely the proper coöperation of infantry, tanks and guns. The seed sown at Cambrai bore rich fruit in the campaign of 1918, but before it could do so Ludendorff was to show that, even without tanks, a break-through was not impossible.

The "Break-through" in 1918.—In discussing the first great French effort to break through the German defensive lines, that

³ It should be noted that the earliest embryo of the tanks made its appearance against Bullecourt in May 1917; but the number of these new engines was then insufficient and their tactics were not well understood. The attack failed, but the date is important historically.

of 1915 in Champagne, it was shown that there were three important causes of non-success—namely, absence of the element of surprise, unsatisfactory cooperation between infantry and artillery, and the fact that the whole enterprise was on too small a scale. In a brief review of later offensives it has been possible to show how these defects were gradually overcome, how artillery gradually dominated the tactical theories of the day, but at the same time rendered surprise an impossibility, until at Cambrai it seemed that the solution had at last been found. But Cambrai was itself something of an experiment, and on too small a scale to have a really decisive result. As is always the case in war, the armies of the Central Powers had been passing all the time through the same evolutionary stages as those of the Entente. The minds of Hindenburg and Ludendorff were busy with exactly the same tactical problems as those which daily occupied the thoughts of British, French and Italian commanders. After the great failure in front of Verdun in the early part of 1916 there was no German offensive on the Franco-British front until March 1918, but much experience had been gained in the East and in Italy; moreover, there can be no doubt that Ludendorff's penetrating mind had grasped the reasons for the failure of successive attacks by the Entente armies, as well as the real meaning and significance of Cambrai. Profiting by the experience of others—always a most difficult thing to do, but perhaps particularly so in war—he had refrained from himself taking the initiative until the Russian *débâcle* had put him in a position to do so on a really grand scale. By March 1918 he was able to mass some 80 well-trained divisions for offensive operations in the West, and this in turn enabled him to attack the British III and V Armies on a front of 80 kilometres.

The mere fact of being able to stage an attack on this scale gave the German armies a great prospect of success, and eliminated the third of the causes of failure enumerated above. The other two were more difficult to deal with, but in order to secure surprise Hindenburg and Ludendorff decided to dispense with that counter-battery work and artillery preparation which on the Somme, at Arras and round Ypres, no less than in Champagne, had disclosed the Allies' intentions while at the same time rendering the ground difficult, and sometimes impossible, to the attacking infantry. Five hours only were allotted to the artillery bombardment, and in this time wire was to be cut and the enemy guns to be mastered at least sufficiently to allow the infantry to advance. Such was the solution of the second problem—the introduction of surprise—and the decision to attempt so much in so short a time was perhaps the bolder since the German army must accomplish without tanks and on a much larger scale what the British had accomplished with them at their last attempt.¹ The third difficulty—that of cooperation—was overcome by the provision of large numbers of light trench mortars,² which, as well as a proportion of field guns, accompanied the infantry advance, as well as by an elaborate system of light signals by which the infantry might indicate their position and wishes to the artillery.

Thus each of the difficulties of 1915 found an appropriate solution in 1918. The attack was on a sufficiently large scale to allow considerable room for manoeuvre within the salient which was inevitably formed, the infantry received adequate support from the artillery, at least for several days, and until it was itself exhausted by appalling loss and by the breakdown of supplies (for which the efficiency of the British air service was largely responsible) on congested roads; lastly, a tactical surprise had been effected, with the result that the troops which bore the brunt of the first onslaught were without reinforcements for several days; and this was principally due to the fact that there was no preliminary bombardment to indicate definitely the portion of the front which had been selected for attack.

¹ The facts that the German design had been foreseen at Versailles and that the evidence of prisoners confirmed the British forecast in no way detract from the tactical skill with which Ludendorff's plans were prepared and executed, or from the value of the lesson.

² It has been said that the Germans possessed 15,000 of these weapons in 1918.

Nevertheless, notwithstanding the admitted skill and care with which the German commanders had prepared their plans and the colossal scale upon which they carried them out, they, no less than the Entente, failed to reach decisive results. What they did was to show what it was possible to achieve with the materials which science and industry had by this time placed in the hands of the commanders in the field. They had shattered many of the shibboleths of trench warfare and shown that infantry was still the conquering arm. In doing so, they not only exhausted their own man-power, but set loose a new set of tactical ideas which were seized by the genius of Marshal Foch and eventually assisted in their own destruction, for, just as Germany had learnt from the Allied successes and failures of 1915, 1916 and 1917, so the Allies in their turn learned from the German success and failure of 1918.

Foch in Command—It is not necessary here to trace the steps which led to the appointment of Marshal Foch to the Supreme Command in March 1918. All that remains to be done is to follow the effect of that appointment upon the tactical history of the war on the western front. Even after the first great German drive had been checked in front of Amiens, the initiative remained with the Germans for more than three months while the great soldier who was now in command of the Allied armies was reorganizing his forces and making his own plans. During this period the German attack tactics were unaltered, but each successive effort was a little weaker than that which preceded it, and the only new development was the skill with which one French commander evaded the enemy's blow, surrendered his forward posts and crushed the assaulting lines as they approached his real fighting positions. Such tactics were only possible at a specially favoured portion of the front, but that they were brought into play at the right place and at the right time was another sign that trench warfare was becoming a thing of the past. Meanwhile Foch was maturing his plans, and when historians of the future, with full documentary evidence at their disposal, examine the record of these days it may be found that the marshal's greatest claim to fame is that he, the student of the past, still retained his belief in the war of movement and in the counter-stroke as the strongest weapon of defence.

Twice in the earlier stages of the war great counter-strokes had been delivered with marked success, but for two years they had not been repeated, and the side which had attacked had been met only with passive defence. In 1914 the German sweep towards Paris had been outflanked by Manoury and thrust back to the line of the Aisne, and nearly two years later the costly attempt to capture Verdun had been checkmated by the opening of the first battle of the Somme, though not until it had been in progress for several months. Since that date there had been the two great Entente attacks of April and July 1917 and the German attack of March 1918. In 1918 troops for the attack were provided by withdrawal from Russia, where they were no longer required; but in 1917 it had been necessary to denude important parts of the front in order to release the number of divisions necessary for offensive action, and to trust for defence to a highly developed trench system which could be held by comparatively few troops, so that there was a considerable risk of counter-attack. It is remarkable that, against an enemy trained in the German traditions, the assailant was always able to impose his will, and the defence became largely a question of railways and transportation. The relief of troops on a fighting front, their replacement by others, and their transport to a quiet part of the line became a regular tactical system to which the French gave the name of *roulement*. It was a new feature of war, completely contrary to the peace teaching of every country, but one which was the logical result of the elaborate preparations which were then considered necessary before it was possible to burst through a modern system of field fortification. It was not until Marshal Foch assumed command that the grand tactics of defence underwent any real change, and perhaps he was fortunate in that Cambrai and the March offensive had shown what was possible, and that, as the result of the movement which had taken place, the positions held by the opposing forces

were unavoidable, but it was found far safer for infantry to run the risk of an occasional short burst than to let the barrage run away from them, leaving them exposed to enemy machine-guns.

Two other points in connexion with the Somme battle are especially worth noting. First, several attempts were made to operate on a really large scale by night, and on one occasion at least considerable success was won. Secondly, tanks made their first appearance, an event of real historic importance.

Nevertheless it must be admitted that 1916 brought the Allies little if any nearer to the longed-for "break-through" than had 1915, and largely for the same reasons. Again it was evident that prolonged bombardment was the enemy of surprise. Again it had been found that the first system of defence was far less difficult to deal with than were the less well-organized and comparatively ill-defined lines in rear. In addition it was discovered that the shell-torn ground opposed a formidable obstacle to the movements of the attacking infantry, while every hole was a ready-made emplacement for a German machine gun.¹ Great things had indeed been achieved both by the British and the French armies but the enemy was not crushed, and after months of fighting on an unprecedented scale he still preserved an unbroken front from the English Channel to the Swiss mountains. This time the explanation was held to be that, after all, the system of limited objectives was wrong, for the delay necessitated by the methodic preparation for each successive attack merely permitted the enemy to recover from the previous reverse, to bring up reserves of infantry and artillery, and to organize a fresh defence. Thus at each stage of the battle the defence grew stronger, and the attack weakened until it at last died from exhaustion. From this premise it followed that if real success was to be won the artillery preparation must be heavier than ever but in greater depth, and the infantry must pass through all the successive lines of defence in one irresistible rush. Such was the teaching of the French official instructions of Dec 1916 which prepared the ground for Gen. Nivelle's disastrous attack in April 1917.

Lessons of 1917.—Unlike its predecessors, the campaign of 1917 was singularly unfruitful in tactical ideas. Partly owing to insufficient preparation, partly to over-confidence and partly to want of secrecy—for it was commonly reported that every flower-seller in Paris knew exactly what was intended—the great French offensive by the IV., V. and VI. Armies met with a severe reverse. The subsidiary attack by the British I., III. and V. Armies was more successful, but again resistance was found more difficult to overcome as the attack progressed, and the operations were finally abandoned when it became evident that the main attack, from which so much had been hoped and expected, could not attain its object.

The principal scene of operations then became the Ypres area. First the capture of the Messines ridge, and then the prolonged attack, in appalling weather and on a narrow front, against the Passchendaele ridge. As had happened on every previous occasion, the first system of enemy defences fell easily enough,² but difficulties increased just when, theoretically, they should have been most easy to overcome. The artillery "preparation," on a scale far greater even than in the Arras battle of April, did its work only too well, for, coupled with the heavy rains, it converted a naturally swampy country into a pock-marked morass, intensifying in a high degree the troubles of the infantry, and greatly curtailing the usefulness of the tanks, which were by this time an important new arm of offense. During this period, too, the use of gas, especially the newly discovered "mustard" variety, became more persistent and more general than ever before. Masks were worn for hours on end, and so impregnated did the soil become that many men suffered merely

¹ In addition the British armies in particular had to overcome almost incredible difficulties in keeping up the requisite supplies of ammunition and food over a country which was almost devoid of roads. It was indeed found necessary to institute a regular road department of the transportation directorate.

² It should also be noted that the perfection (coupled with ample supply) of instantaneous fuzes now made the destruction of wire defences a far simpler affair than it had been before.

from sitting or lying down to rest. Never has any army fought under greater disadvantages than did the British during the autumn of 1917, yet, even if it did not do what was hoped from it, it is only necessary to read Ludendorff's account to realize how heavy was the strain upon the German resources. Moreover, under the leadership of Hindenburg and Ludendorff, the defensive strategy and tactics of the German army had been radically overhauled during the winter of 1916-7, and the *moral* of the troops had been wonderfully improved. Indeed, the army which held the French on the Aisne, the British at Arras and the combined Allies round Ypres was altogether different in spirit from that which had been hunted back to the Hindenburg line during the previous winter. Even the air service responded to the new spirit, and the Entente troops no longer enjoyed the immunity from bomb attacks which had been theirs throughout 1916, far from it. Such was the effect of the masterful and trusted leadership which now had control of the German army.

Tactically, the principal change brought about by the new régime was a greater elasticity in defence, which aimed at affording as ill-defined a target as possible to the attacking artillery and the vaguest possible objective to the assaulting waves of infantry. In reserve were held certain battalions whose duty it was to advance to the counter-attack as soon as it was known that an attack had been launched, and thus it came about that more than once infantry which was in process of organization and consolidation after a successful attack found itself thrown upon the defensive and perhaps forced back from a position which had been dearly won. Special aeroplanes were detailed to look out for these counter-movements, and special batteries to deal with them, sometimes by putting down a defensive barrage of gas, and from these small beginnings grew up that war of movement which gradually reasserted itself and increased in intensity until at last the war was lost and won. More and more as the great attacks, whether French, British or combined, failed to win a decisive result, it was realized that in some way or another the element of surprise must be reintroduced, for without it the offensive was deprived of almost half its power. But the question was, How could the enemy defences be overcome without the preliminary bombardment which inevitably "gave away" the assailant's intended plans? The solution of the problem was at last found in the use of tanks, and at the battle of Cambrai tanks came into their own.³ Massed secretly by night conveniently near the objective, and advancing when the time came under cover of an artillery barrage, but over ground which had not been rendered impassable by tons of heavy shell, the tanks effected a complete surprise, passed line upon line of defences, and enabled supporting infantry to occupy an important area of ground with but little loss. So severe had been the drain upon the German reserves during the Ypres fighting that for some twenty-four hours the British troops were within an ace of really effecting a break-through, and Ludendorff has himself said that if they had been able to push on a little farther they might have broken in upon his communications and so have scored a considerable strategical success. But the drain upon the British reserves had been no less heavy than upon the German, and the necessary weight to turn a tactical victory into a strategical success was just lacking. In the end Ludendorff was able to mass troops for a counter-attack, and some of the ground which had been lost was re-won; but for the Allies by far the most important result of the Cambrai fighting was that the "trouistes" had been able to justify the faith which was in them and to show that there was a way leading to decisive victory—namely the proper coöperation of infantry, tanks and guns. The seed sown at Cambrai bore rich fruit in the campaign of 1918, but before it could do so Ludendorff was to show that, even without tanks, a break-through was not impossible.

The "Break-through" in 1918.—In discussing the first great French effort to break through the German defensive lines, that

³ It should be noted that the earliest embryo of the tanks made its appearance against Bullecourt in May 1917; but the number of these new engines was then insufficient and their tactics were not well understood. The attack failed, but the date is important historically.

1918; but that which followed was not the open warfare of Frederick the Great, Napoleon or Wellington. Even to the very end, in Nov., the opposing lines were continuous for 300 miles, and no open flank afforded opportunity for crushing defeat. Local flank attacks there were in plenty, and some on quite a big scale, but there was no Waterloo or Sedan. It had been a national war, and the German nation had suffered a crushing national defeat; but even when the Emperor had deserted and fled ignominiously to Holland the beaten army was still able to withdraw across the Rhine in some semblance of order.

Palestine.—Different in almost every respect, and therefore also in the tactics employed, were the campaigns conducted in parts of the world outside Europe. This was especially so in Palestine, and for that reason will it be well to devote some space to the special conditions of that theatre of war and upon the resulting conduct of operations. In the first place the theatre of war was practically a neutral country. Nominally a part of the Turkish Empire, Palestine was in actual fact extra-national, or extra-imperial, with a population by no means united or enthusiastic in support of the Turkish power. The Russo-Japanese War offers another, and even more remarkable, instance of a quarrel between two nations being settled on the territory of a third. In such conditions the war can have none of those national characteristics which formed such a dominating and distinctive feature of the war in the west of Europe. This was the fundamental difference between the main campaign and the subsidiaries, from which it came about that the defeat of Turkey was less national and far more military than was the defeat of Germany. A second important feature of difference is to be seen in the railway development of the theatre of war. It is only through a complete network of railways, supplemented by road transport, that a nation is able to concentrate the whole efforts not only of its manhood, but of its entire population upon the one purpose of winning a war, just as in peace the whole efforts of a population are concentrated upon various forms of industry. When the necessary conditions are lacking, the resultant warfare must inevitably be, if not exactly more primitive in form than in a highly developed country, at least nearer to that waged by the professional armies of the past.

The preparatory stages of this campaign, including the Turkish raids against the Suez Canal and the subsequent advance to El Arish and the neighbourhood of Gaza, need not detain us beyond noting the construction of the broad-gauge railway from Kantara across the Sinai desert. It was wise strategical and tactical foresight which had led Allenby's predecessor, Sir A. Murray, to insist upon a broad-gauge line and so be prepared for operations on a large scale instead of yielding to the temptation to content himself with a narrow-gauge line, which could have been more easily and rapidly constructed and would have sufficed for his own immediate requirements. A false, or at least a different, decision on his part in the spring of 1916 would have had a most hampering effect upon subsequent operations, of which it was at that time only possible to foresee the most shadowy possibility.

For the purely tactical study, we may pass at once to the period of Lord Allenby's command and the advance in Palestine. This period may itself be divided into two phases: first, that campaign which began with the capture of Beersheba on Aug. 31 1917 and culminated in the entry into Jerusalem on Dec. 11 of the same year, secondly, the dramatic series of operations which, between Sept. 19 and Oct. 26 1918, resulted in the destruction of the IV, VII and VIII Turkish Armies.

Allenby's strength in mounted men was significant of the possibilities of the theatre in which he was to operate. In discussing the development of the tactics on the western front no mention has been made of the mounted arm, simply because after the first weeks of the war it had no scope for acting in its peculiar sphere; there was no scope for mobility and the mounted man never really found his opportunity. It was exactly the reverse with the Palestine campaign. So we find that in all these operations the infantry gets from the cavalry or other mounted troops far more of the support which it always requires

and from the artillery far less. There are no long preliminary bombardments, for as a rule there are neither guns nor targets, but in the very first operation undertaken, the capture of Beersheba, "a mounted attack by Australian Light Horse, who rode straight at the town from the east, proved completely successful. They galloped over two deep trenches held by the enemy just outside the town, and entered the town about 7 P.M., capturing numerous prisoners."¹ In passing, it is worth noting that the operation against Beersheba was undertaken expressly because "when it was in our hands we should have an open flank against which to operate, and I could make full use of our superiority in mounted troops"; and again, when the city had been taken, with 2,000 prisoners and thirteen guns. "This success laid open the left flank of the main Turkish position for a decisive blow." Surprise and movement had taken the place of costly infantry assaults, simply because local conditions had made them possible.

Exactly the same experience was repeated in the second stage of this campaign, which began in Sept. 1918 and ended when the armistice came into force on Oct. 31. At the commencement of these operations the Egyptian Expeditionary Force was holding a line from the river Jordan on the right to a point where the left rested on the Mediterranean coast, 10 miles north of Jaffa. The total fighting strength of the force was 12,000 mounted men, 57,000 infantry and 540 guns. Opposing them, the Turkish IV Army watched Lord Allenby's right on the Jordan, in the centre was the VII Army on a front of some 20 miles, while on the right was the VIII Army holding a similar length of front. Including reserves, but excluding certain posts on the Hejaz railway which were more than fully occupied defending themselves against the Arabs, the Turkish commander-in-chief had at his disposal some 4,000 mounted men, 26,000 infantry, with 400 guns, by no means a strong force with which to stand on the defensive on a front of over 50 miles against an active and resolute enemy.

Allenby's numerical superiority, it will be noted, was especially in mounted men, and this he decided to turn to full advantage when he resolved to make Nazareth, a good 40 miles to the north, the objective of his next advance, but to set his cavalry free it was first necessary for the infantry and artillery to force an opening through the Turkish front. By using every device to deceive the enemy as to his intentions, Allenby was able to concentrate 35,000 rifles and 383 guns on his left, where they were opposed by no more than 8,000 rifles and 130 guns, while two cavalry divisions and one Australian mounted division were immediately available.² The infantry attack was launched at 4.45 A.M. on Sept. 19 after an artillery bombardment lasting no more than fifteen minutes, the exact object of which is not clearly evident. The attack was completely successful, and the cavalry, dashing through the opening afforded to them, seized the communications and closed all lines of retreat to the north. Nazareth was entered on the second day of the operations, and four days later "the last remnant of the Turkish VII and VIII Armies had been collected." The IV Army met the same fate only a few days later, and on Oct. 1 the Arab army and Allenby's Mounted Corps entered Damascus, which lies nearly 100 miles in a straight line to the north-east of Nazareth. Still pressing northward, and completing as they went the unutterable destruction of the Turkish armies, the mounted troops, with a few armoured cars, entered Aleppo, more than 200 miles north of Damascus, on Oct. 26, and when the armistice was signed on the 31st were within striking distance of Alexandria.

II—TACTICS AFTER THE WORLD WAR

An effort has been made so far to give in outline some idea of the tactical conditions on the western front and in Palestine,

¹ From Lord Allenby's despatch, dated 16.12.1917:—"What would not the British or French cavalry on the western front have given for such an opportunity! But wire, mud, shell holes, and especially German machine guns, effectually prevented any such possibility."

² Lord Allenby's despatch, dated 31.10.18.

the methods resulting from these conditions, and the results achieved. Utterly dissimilar as were these two theatres of war, the underlying principles of victory are found, as always, to be the same. A firm faith in the offensive, concentration at the right time and against a suitable objective, surprise, and co-operation. The welding of all the forces, moral and physical, by the genius of the commander into one homogeneous whole, with one common inspiration, and directed to a common objective, namely victory. So far the two campaigns selected for illustration are in agreement with one another and with all the campaigns of the past, in every other respect the contrast is complete. On the one hand, in France and Flanders we find whole nations in arms, troops numbered by hundreds of thousands, and, as a necessary corollary, continuous lines, heavily fortified and without flanks to be turned, almost (one might say) without any vital line of communications, so complete were the railway and road systems available. As the result—long periods of stagnation, infantry deriving no assistance from the mounted troops (except indeed when acting dismounted), and dependent in the first place upon artillery and latterly upon tanks as well. Movement, when at last it comes, is by slow stages, until when victory is won it is by the crushing of a nation rather than of the armies in the field alone; for this was national war. On the other hand, in Palestine we find armies operating in a neutral arena, small in numbers with open flanks to the east, and each dependent upon a single line of railway, scope and objective not only for trained and disciplined mounted troops, making full use of their mobility, but also for light rapid-moving Arab levies harrying the Turkish communications, and achieving great strategical and tactical results, with but little loss to themselves, entirely by the power of movement. Artillery here plays but a secondary or even lesser rôle, for instead of congestion there is space—space in plenty, and when that element is present light troops come into their own; activity takes the place of force, and victory is over the field armies rather than over the civil population.

Between the two extremes of the western European front and Palestine lay such other campaigns as Mesopotamia and Macedonia, but these, though interesting enough in themselves, add nothing to our present purpose and seem only to emphasize the same theory in less convincing form—namely that each theatre of war, by its own distinctive physical features and climate, influences, if it does not actually dictate, the tactics by which battles and campaigns are won. Otherwise war might become an exact science instead of the most difficult of the arts.

This war of 1914-8, then, by its very size and variety, has solved no tactical problem, has answered none of the questions left by S. Africa in 1899-1902, or Manchuria in 1904-5, but, like all its predecessors, has raised many new ones. Strategy is still the art of bringing the enemy to battle on terms which are disadvantageous to him; tactics are still the methods employed for his destruction. In former wars this most desirable object was accomplished by a judicious combination of artillery, cavalry and infantry. To-day the object is the same, but the means have been complicated to a degree which in 1910 was altogether beyond human imagination. Railways have completed the work of Carnot and the French revolutionary generals, and made national war a complete reality; but through the perfections of the internal-combustion engine war itself has taken on a third dimension. If a great master was formerly required properly to handle and combine the comparatively primitive means at his disposal, how much greater should the artist now be who is to use, and not to waste, the much more complicated tools which science has now placed in his hands. As science advances the art becomes more complex, things tend to become greater than men, and use more difficult than invention. Always change has followed along the same line, but so rapid have been the latest steps that the armies of 1921 were further from those of 1821 than Napoleon's armies were from those of Hannibal; yet the human imagination and capacity remain as they were two thousand years ago.

All through the ages changes in tactics have been brought about by improvements in the means of killing. Latterly

science has advanced with giant strides, yet the mechanism of slaughter appears to be only in its infancy. How difficult, therefore, to foresee even with what weapons later wars may be fought, and what may be the next steps in tactical evolution. It is easy, indeed, to let the imagination run riot, and to picture whole populations destroyed by infernal machines easily and efficiently controlled by wireless waves. The pebble is to be thrown in at Berlin, Stockholm, Moscow or anywhere else you will, and the influence carried to the uttermost parts of the earth. Equally easy it is to persuade oneself that there will be no change, and the next war will begin exactly where the last left off. History teaches us, unfortunately, that neither of these views is likely to be exactly fulfilled. Possibly they serve as useful correctives one to the other; but the difficulty is to strike the happy medium. When so many new questions have been raised and so few old ones have been answered, only one definite new principle seems to have been established. It is that, more than ever before, tactical methods must vary in accordance with the theatre of operations, and that methods suitable to one country are unsuitable to another. Indeed even this is hardly new, since it is clear that methods which sufficed to overthrow the Mahdi at Omdurman would have been quite unsuitable against the Boers in S. Africa. A short time ago we were satisfied with two classes—"normal warfare" and "savage warfare"; that is to say, war against highly trained, well-equipped professional armies or against primitive races, of which every able-bodied man was an ill-equipped untrained soldier. Those distinctions no longer suffice. Here there is an initial difficulty, for in trying to imagine the tactics of the future we must first imagine the conditions under which war will be fought. Will they resemble the conditions of France and Flanders, of Macedonia, Mesopotamia or Palestine?

Conditions for Future Wars—One thing is certain, that the wit of man cannot devise a system which will be equally suitable for all. Principles there are, but nothing more. This is especially a British difficulty, for no army of the world is called upon to fight under such varying conditions as is the British, moreover, the British army of modern history has never fought in its own country. It is only necessary to reflect upon the history of the World War of 1914-8 to realize that, while Germans fought almost entirely on their own frontiers, if not in Germany, Frenchmen in France, Italians in Italy, Turks and Bulgarians in Turkey and Bulgaria, the British army and troops from the British Dominions and India fought all over the world. French troops, it is true, fought in many distant campaigns, but except at Salonika the overseas campaigns were preponderantly British, and cannot be considered apart from the British Dominions and India. The only other countries at all in like position are America and Japan, with few extra-territorial commitments.

As a further branch of this same problem we must for a moment consider the troubles of organization and equipment which are inseparable from those of tactics. The French army exists for the defence of France, the Italian army for the defence of Italy. Defence, no doubt, includes offensive action, especially in the case of Germany, but how simple these tasks seem compared with that imposed upon Great Britain with all her world-wide interests. It is easy to see with what confidence the general staffs of continental European nations can address themselves to their well-defined problems, and how much more complex are the manifold problems of the British general staff. Others can fortify their frontiers. Not so Great Britain or her Dominions, who must always be prepared to fight overseas in some theatre of war which cannot be foreseen with any degree of confidence or certainty. That is one fundamental and special complication, as the result of which tactics, organization and even equipment must always, from a British point of view, be something of a compromise, ready and able to be adapted to special conditions on the actual outbreak of war.

Let us consider for a moment what is to be the future of trench warfare. Will future wars reproduce the conditions of 1914 which led up to it? Will it be the normal warfare of the future, or was it no more than a passing phenomenon? Is it

desirable or not to organize, train and equip modern armies with a view to it?

The only possible answer to these questions is that nobody knows. Similar conditions would no doubt produce similar results, but are we likely to find them? What we know beyond the possibility of doubt is that in 1914-8 highly developed industrial countries with dense populations were fighting on or near their own borders. It was these conditions which made possible a war on a front of hundreds of miles, and we may well ask if they can be found again, and, if so, where? Probably the answer would be that only nations possessing the greatest possible resources could support a war of this kind, and that those nations are extremely limited in number, even more limited in 1921 than they were in 1914. Trench warfare in its extreme form is the direct outcome of the industrial revolution of the nineteenth century, and is not possible between such nations, for instance, as Russia and Poland.

But there is more than this. It must also be remembered that trench warfare came in 1914-5 as a surprise, and that all armies dropped into it quite unconsciously. It began with a few strands of ordinary wire laid out in front of simple old-fashioned fire trenches. It was indeed a strange phenomenon. In place of the rapid decision for which everyone had looked, the largest armies the world had ever seen were peering at one another through their screens of metal. That was late in 1914, just at the moment when all the belligerents had practically run out of gun ammunition, when there was no means of dealing with such an unexpected obstacle, and neither side could get at the other. Nothing like this had ever been seen in war. As we now know, it took four years to find the way out of the impasse, but the important point to note is that after the war every nation possessed the antidote. With masses of artillery, instantaneous fuzes and tanks, is trench warfare of this type in any circumstances conceivable? One thing at least seems to be certain, and that is that, having learnt their lesson, the armies of all nations will strain every nerve to render it impossible, and to avoid a repetition of the wearisome experience of 1914-8.

If this means anything at all it is that future wars between civilized nations will be opened with a suddenness and violence far in advance of 1914. In past wars there have always been a few days of grace between the declaration of war and the first serious collisions. In 1914 Germany issued orders for her general mobilization on Aug. 1, France declared war on the 3rd, the Belgian frontier was crossed by Germans on the 4th and by France on the 6th, Liège was entered on the 7th, and the last forts were captured on the 15th; finally the field armies came into collision on the 17th and 18th. Meanwhile on the southern front the French occupied Mulhausen on the 8th with covering troops, but failed to hold it, and it was not until the 14th that their I. and II. Armies and the Alsace group were mobilized and ready to advance into Alsace and Lorraine.

Now, in considering the strategy or the tactics of the opening phases of any future campaign, it was very difficult in 1921 to divest the mind of the picture of 1914, and to remember that there no longer existed in Europe two great military nations with armies magnificently led, fully organized and separated only by an almost imaginary line called a frontier. Something of the sort, it is true, may be found in the borders of France and Italy, but a formidable mountain range only to be traversed by troops at certain well-defined points introduces an important factor which was absent in 1914. Other open frontiers also remained in 1921, notably between Germany and Poland, between Poland and Russia, and still between France and Germany; but, for the time at all events, organized well-equipped armies no longer existed as we knew them in 1914, except in the cases of France and Italy. Nevertheless it is necessary to look forward. Germany, no doubt, had been forbidden by the Peace Treaty to maintain an army of more than 100,000 men, but it was by no means impossible that before many years had passed several of the more backward nations of Europe would become rich and prosperous, with great industries and extensive railway systems, and would be unable to deny themselves the

luxury of great standing armies and all the paraphernalia of war. History, at least, is not encouraging in this respect, and it would certainly be most unwise to assume that, because the necessary conditions of a first-class war were no longer visible in Europe in 1921, they would remain so for ever, or even for a very long time; moreover, it cannot be forgotten that the opening years of the twentieth century saw a first-class war far outside the confines of the European continent.

No excuse is, therefore, necessary for the assumption, in 1921, that coming generations would know war even as the present generation has known it, and that its opening phases would not be so very unlike those of 1914, always with such difference as is brought about by the scientific development of engines of destruction. If this assumption is justified—and it is absolutely necessary to make some assumptions—the prospect is that either there will be no declarations of war, or that by various means the period of mobilization will be very much shortened and the great collisions will take place much more rapidly than before. And this with two objects, partly to avoid trench warfare and to reach a rapid decision, partly to ensure that fighting shall take place on enemy territory and not in the homeland. These objects are in their essence strategical, but will naturally find themselves reflected in the tactical sphere. In the first place, with a view to protecting themselves from a sudden inrush, nations may have to spend vast sums upon the fortification of their frontiers, as France did after 1870, and as Germany did for ten years prior to 1914. The influence of these great fortifications and their ultimate fate are not, however, very encouraging, and it is more probable that money may be spent upon the equipment of field armies, and that very special attention may be paid to the success of the first inroad into enemy territory, to seizing the initiative, upsetting the enemy's plans and insuring that at least the opening battles are fought upon his soil.

Tanks and Aeroplanes.—For these purposes great use will presumably be made of aeroplanes, and rapid-moving tanks acting in company with cavalry and horse artillery, and here we are at once upon highly speculative ground—since the tactical value of these new services is still uncertain. There is a fascination in dreaming of possibilities, but experience shows that tactical development has always proceeded by the slow processes of evolution rather than by revolution, and notwithstanding the great successes achieved by tanks towards the end of the World War, it is difficult to believe that they will be able to act alone for any great length of time. In this connexion it must always be remembered that at the end of 1918 tanks had the enormous advantage of still being something of a surprise. They were constantly improving in efficiency and numbers, and through bitter experience correct tactical methods were gradually evolved. More important than all, even up to the end of the war anti-tank defence was ineffective, an advantage which the new arm cannot expect to enjoy even at the beginning of future campaigns. Even with this great advantage in their favour tanks were vulnerable, and at Hooge and even at Cambrai it was seen that boldly handled artillery could, on occasion, inflict great damage. Increased speed and improved mechanism will render tanks less vulnerable, but against them must be set such possible defence as light easily hidden artillery and anti-tank guns. Indeed, there is just a possibility that future years may see a competition, not unlike that at sea, between gunnery in its various branches on the one hand and speed coupled with armour on the other. The tank will endeavour to combine mobility for offensive action with its own protection, while the gunner and rifleman will try to force the tank to carry armour so heavy as to destroy its mobility. Something of this kind was actually seen in the case of the German tanks, which, in the effort to afford security to their crews, had been so solidly constructed as to be almost useless. Another difficulty from which tanks may suffer is inability to carry out their own reconnaissance in moving warfare. Tanks would also appear to be almost as defenceless at night as is artillery, they are indeed entirely an offensive weapon except for the actual protection which their armour affords to the crews. For these reasons tanks would

the methods resulting from these conditions, and the results achieved. Utterly dissimilar as were these two theatres of war, the underlying principles of victory are found, as always, to be the same. A firm faith in the offensive, concentration at the right time and against a suitable objective, surprise, and coöperation. The welding of all the forces, moral and physical, by the genius of the commander into one homogeneous whole, with one common inspiration, and directed to a common objective, namely victory. So far the two campaigns selected for illustration are in agreement with one another and with all the campaigns of the past, in every other respect the contrast is complete. On the one hand, in France and Flanders we find whole nations in arms, troops numbered by hundreds of thousands, and, as a necessary corollary, continuous lines, heavily fortified and without flanks to be turned, almost (one might say) without any vital line of communications, so complete were the railway and road systems available. As the result—long periods of stagnation, infantry deriving no assistance from the mounted troops (except indeed when acting dismounted), and dependent in the first place upon artillery and latterly upon tanks as well. Movement, when at last it comes, is by slow stages, until when victory is won it is by the crushing of a nation rather than of the armies in the field alone; for this was national war. On the other hand, in Palestine we find armies operating in a neutral arena, small in numbers with open flanks to the east, and each dependent upon a single line of railway, scope and objective not only for trained and disciplined mounted troops, making full use of their mobility, but also for light rapid-moving Arab levies harrying the Turkish communications, and achieving great strategical and tactical results, with but little loss to themselves, entirely by the power of movement. Artillery here plays but a secondary or even lesser rôle, for instead of congestion there is space—space in plenty, and when that element is present light troops come into their own; activity takes the place of force, and victory is over the field armies rather than over the civil population.

Between the two extremes of the western European front and Palestine lay such other campaigns as Mesopotamia and Macedonia, but these, though interesting enough in themselves, add nothing to our present purpose and seem only to emphasize the same theory in less convincing form—namely that each theatre of war, by its own distinctive physical features and climate, influences, if it does not actually dictate, the tactics by which battles and campaigns are won. History teaches us, unfortunately, that neither of these views is likely to be exactly fulfilled. Possibly they serve as useful correctives one to the other; but the difficulty is to strike the happy medium. When so many new questions have been raised and so few old ones have been answered, only one definite new principle seems to have been established. It is that, more than ever before, tactical methods must vary in accordance with the theatre of operations, and that methods suitable to one country are unsuitable to another. Indeed even this is hardly new, since it is clear that methods which sufficed to overthrow the Mahdi at Omdurman would have been quite unsuitable against the Boers in S. Africa. A short time ago we were satisfied with two classes—"normal warfare" and "savage warfare"; that is to say, war against highly trained, well-equipped professional armies or against primitive races, of which every able-bodied man was an ill-equipped untrained soldier. Those distinctions no longer suffice. Here there is an initial difficulty, for in trying to imagine the tactics of the future we must first imagine the conditions under which war will be fought. Will they resemble the conditions of France and Flanders, of Macedonia, Mesopotamia or Palestine?

Conditions for Future Wars—One thing is certain, that the wit of man cannot devise a system which will be equally suitable for all. Principles there are, but nothing more. This is especially a British difficulty, for no army of the world is called upon to fight under such varying conditions as is the British, moreover, the British army of modern history has never fought in its own country. It is only necessary to reflect upon the history of the World War of 1914-8 to realize that, while Germans fought almost entirely on their own frontiers, if not in Germany, Frenchmen in France, Italians in Italy, Turks and Bulgarians in Turkey and Bulgaria, the British army and troops from the British Dominions and India fought all over the world. French troops, it is true, fought in many distant campaigns, but except at Salonika the overseas campaigns were preponderantly British, and cannot be considered apart from the British Dominions and India. The only other countries at all in like position are America and Japan, with few extra-territorial commitments.

As a further branch of this same problem we must for a moment consider the troubles of organization and equipment which are inseparable from those of tactics. The French army exists for the defence of France, the Italian army for the defence of Italy. Defence, no doubt, includes offensive action, especially in the case of Germany, but how simple these tasks seem compared with that imposed upon Great Britain with all her world-wide interests. It is easy to see with what confidence the general staffs of continental European nations can address themselves to their well-defined problems, and how much more complex are the manifold problems of the British general staff. Others can fortify their frontiers. Not so Great Britain or her Dominions, who must always be prepared to fight overseas in some theatre of war which cannot be foreseen with any degree of confidence or certainty. That is one fundamental and special complication, as the result of which tactics, organization and even equipment must always, from a British point of view, be something of a compromise, ready and able to be adapted to special conditions on the actual outbreak of war.

Let us consider for a moment what is to be the future of trench warfare. Will future wars reproduce the conditions of 1914 which led up to it? Will it be the normal warfare of the future, or was it no more than a passing phenomenon? Is it

artillery equipment, fast-moving tanks should give to cavalry or mounted infantry an invaluable reinforcement in fire power. It is the weakness of mounted troops that whenever they are called upon to use fire one-fourth of the personnel is out of action, merely taking care of their horses; and this at the critical moment of action. No such disability handicaps the tanks, whose fire power is great in proportion to the personnel employed. They will, therefore, supply exactly the factor in which mounted troops are necessarily weak, while their own peculiar drawback, vulnerability to fire from artillery or specially constructed rifles, will be of little account. Mechanical difficulties, from heat and other causes (for the strain upon the crew in a closely confined space is always great), they will certainly have, but these should not be insuperable and may be disregarded. A mixed force of tanks and mounted troops should therefore have just that combination of mobility and fire power which is necessary to allow civilized troops to make free use of space—that is, to manoeuvre freely and confidently—against an uncivilized or ill-equipped enemy before his *moral* has been shaken.

Exactly the same arguments apply to tanks acting with infantry and artillery in a formal attack against an uncivilized enemy in position. The mere fact that such an enemy does not himself possess tanks will add enormously to the moral effect of their appearance, and should go far toward rendering an artillery preparation or bombardment of any kind unnecessary. If this is so, surprise becomes much more simple, and surprise is, as always, the strongest weapon of the attack. It is evident, therefore, that at every stage the older arms will be wonderfully strengthened by new inventions, yet it cannot be claimed that even in second- or third-class warfare science has yet succeeded in producing anything entirely to take the place of the man and the horse, for the man and the horse are, after all, the only pieces of mechanism which are adaptable to varying circumstances, yet perfect in themselves and directed by an individual intelligence. Science then does not as yet supersede the most primitive factors in war, but where one side has the monopoly of its products (or even only of some of them) there should be economy of effort, and consequently of life, which should enable the civilized army to be always on the offensive and to force a favourable decision with great rapidity.

Lessons of 1914-8—To sum up, then, the experiences of the past war and the effects of the latest discoveries, it would seem that at first the defensive proved to be a far stronger form of warfare than had been anticipated, because, owing to dense populations and good communications, armies could hold continuous lines, with no open flanks. Frontal attacks of the most pronounced kind became unavoidable, and months and even years passed before the attack regained its ascendancy. In these conditions there was no scope for the mounted arm, and even the infantry returned to the most primitive form of warfare. Rifle-fire was useless, for it could not kill, and fire which does not kill is wasted. It was then that the infantry had recourse to the bayonet and the bomb, and the long-range fighting of S. Africa ceased to be. Instead, for three whole years infantry tactics were on a lower and less scientific plane than in the Manchurian War, which, in the opinion of many soldiers, was fought out on altogether a lower plane than the S. African War which preceded it. Meanwhile ever-growing demands were made upon the artillery, not only for increased weight of projectile and volume of fire, but for a degree of accuracy which had never before been considered necessary or even possible. So far did the dependence of the infantryman upon artillery support extend that there were some who advocated the abolition of the rifle altogether, since it could no longer kill. Then came two vitally important inventions—first, the instantaneous fuse, which deprived wire of much of its terror, and then tanks, with their combination of mobility and fire. With tanks and artillery, infantry recovered its power of movement, and with movement the rifle recovered its position, for trenches had lost their protective value and once more it could kill in the open. In less civilized warfare we can see that on a narrow space like the Gallipoli peninsula continuous lines were possible, but elsewhere

space gave freedom for movement, fire was supreme, and the victor imposed his will by crushing the enemy's field armies. In both forms of warfare it was proved once more that in the end infantry is still the queen of battle, but requires ever more assistance from the other arms and from science.

Now, in this very question of the influence of scientific discovery upon tactics, the World War has taught us much. But need the experience have been quite so bitter? No doubt it is easy to be wise after the event, but we should learn little if we allowed ourselves to be convinced that we were perfectly wise before it. To take only one instance, the enormous expenditure of gun ammunition during the opening weeks of the war had the effect of entirely using up all reserves within a very short time after the opening of hostilities. It is now no secret that by the end of the first battle of Ypres the British artillery was practically without ammunition, guns were rare enough, but even the few there were had nothing to fire. And this was true of all armies. It was not only the weather which stopped the fighting in the middle of Nov., it was, as well, largely the fact that infantry was almost deprived of artillery support. Moreover, it was just this period of respite which enabled the armies to dig themselves in, and to organize those systems of field fortification which for so long defied assault. Now, this deficiency was due to two causes. In the first place to a short-sighted economy, always in favour of running a risk in order to avoid unpleasant parliamentary criticism—and this tendency exists in all countries; in the second place, it was due to a tendency, which is also universal, to devote too much attention to the past and too little to the future. It is so easy to follow Napoleon's advice, to read and reread the campaigns of the great commanders; it is so easy to store the mind with facts and figures, but it is so difficult to apply the knowledge acquired to the requirements of the future and to breathe life into Dryasdust. This is, perhaps, the most difficult task of the general staffs, which all nations had by 1911 established more or less upon the Moltke model. Every great army has its inventions board, whose duty it is to sift the corn from a vast quantity of useless chaff, but the real trouble is to foresee what the tactical effect of any new discovery may be and how to turn it to advantage upon the field of battle. It is easy to learn by experience, but wonderfully difficult to prophesy. Some instances there have been, notably Wellington's confidence that, with the weapons he had, he could dare to go into battle in new formations giving him unprecedented fire power. By his penetrating insight he gained a very definite advantage over men whose experience in European warfare was infinitely greater than his own, and, by breaking away from the stereotyped lines rendered classic by Frederick the Great and even by Napoleon, British infantry gained a tactical advantage which they retained until Waterloo. It was exactly the same firm and traditional belief in the efficacy of rifle-fire which won the first battle of Ypres, for at least in this respect nothing approaching the training of the British Expeditionary Force had ever been seen in European armies. Similarly, it was Moltke's realization of the power of improved weapons and other developments of science that was the origin of his idea of envelopment, whereby he revolutionized German tactics and crushed the armies of Austria and France. Both commanders took risks which are now difficult to realize, but both were justified, not only by their own victories, but by subsequent history. Wellington and Moltke both had their critics, but there is no one who now doubts the wisdom of linear formations or enveloping tactics.

It is unfortunately impossible to produce a Wellington or a Moltke at will, but the application of the lessons of history to the requirements of the future is at least as important and needs at least as much study as the facts themselves. With each step forward and as science renders more and more services to the great art of war the future becomes more difficult to forecast. In the first place it is evident that, as war becomes more complex, peace manoeuvres must become less and less realistic. It is related that Frederick the Great regularly rehearsed the movements with which he intended to beat the Austrians. We are also told that the comment of the victorious Prussian soldiers

the methods resulting from these conditions, and the results achieved. Utterly dissimilar as were these two theatres of war, the underlying principles of victory are found, as always, to be the same. A firm faith in the offensive, concentration at the right time and against a suitable objective, surprise, and co-operation. The welding of all the forces, moral and physical, by the genius of the commander into one homogeneous whole, with one common inspiration, and directed to a common objective, namely victory. So far the two campaigns selected for illustration are in agreement with one another and with all the campaigns of the past, in every other respect the contrast is complete. On the one hand, in France and Flanders we find whole nations in arms, troops numbered by hundreds of thousands, and, as a necessary corollary, continuous lines, heavily fortified and without flanks to be turned, almost (one might say) without any vital line of communications, so complete were the railway and road systems available. As the result—long periods of stagnation, infantry deriving no assistance from the mounted troops (except indeed when acting dismounted), and dependent in the first place upon artillery and latterly upon tanks as well. Movement, when at last it comes, is by slow stages, until when victory is won it is by the crushing of a nation rather than of the armies in the field alone; for this was national war. On the other hand, in Palestine we find armies operating in a neutral arena, small in numbers with open flanks to the east, and each dependent upon a single line of railway, scope and objective not only for trained and disciplined mounted troops, making full use of their mobility, but also for light rapid-moving Arab levies harrying the Turkish communications, and achieving great strategical and tactical results, with but little loss to themselves, entirely by the power of movement. Artillery here plays but a secondary or even lesser rôle, for instead of congestion there is space—space in plenty, and when that element is present light troops come into their own; activity takes the place of force, and victory is over the field armies rather than over the civil population.

Between the two extremes of the western European front and Palestine lay such other campaigns as Mesopotamia and Macedonia, but these, though interesting enough in themselves, add nothing to our present purpose and seem only to emphasize the same theory in less convincing form—namely that each theatre of war, by its own distinctive physical features and climate, influences, if it does not actually dictate, the tactics by which battles and campaigns are won. Otherwise war might become an exact science instead of the most difficult of the arts.

This war of 1914-8, then, by its very size and variety, has solved no tactical problem, has answered none of the questions left by S. Africa in 1899-1902, or Manchuria in 1904-5, but, like all its predecessors, has raised many new ones. Strategy is still the art of bringing the enemy to battle on terms which are disadvantageous to him; tactics are still the methods employed for his destruction. In former wars this most desirable object was accomplished by a judicious combination of artillery, cavalry and infantry. To-day the object is the same, but the means have been complicated to a degree which in 1910 was altogether beyond human imagination. Railways have completed the work of Carnot and the French revolutionary generals, and made national war a complete reality; but through the perfections of the internal-combustion engine war itself has taken on a third dimension. If a great master was formerly required properly to handle and combine the comparatively primitive means at his disposal, how much greater should the artist now be who is to use, and not to waste, the much more complicated tools which science has now placed in his hands. As science advances the art becomes more complex, things tend to become greater than men, and use more difficult than invention. Always change has followed along the same line, but so rapid have been the latest steps that the armies of 1921 were further from those of 1821 than Napoleon's armies were from those of Hannibal; yet the human imagination and capacity remain as they were two thousand years ago.

All through the ages changes in tactics have been brought about by improvements in the means of killing. Latterly

science has advanced with giant strides, yet the mechanism of slaughter appears to be only in its infancy. How difficult, therefore, to foresee even with what weapons later wars may be fought, and what may be the next steps in tactical evolution. It is easy, indeed, to let the imagination run riot, and to picture whole populations destroyed by infernal machines easily and efficiently controlled by wireless waves. The pebble is to be thrown in at Berlin, Stockholm, Moscow or anywhere else you will, and the influence carried to the uttermost parts of the earth. Equally easy it is to persuade oneself that there will be no change, and the next war will begin exactly where the last left off. History teaches us, unfortunately, that neither of these views is likely to be exactly fulfilled. Possibly they serve as useful correctives one to the other; but the difficulty is to strike the happy medium. When so many new questions have been raised and so few old ones have been answered, only one definite new principle seems to have been established. It is that, more than ever before, tactical methods must vary in accordance with the theatre of operations, and that methods suitable to one country are unsuitable to another. Indeed even this is hardly new, since it is clear that methods which sufficed to overthrow the Mahdi at Omdurman would have been quite unsuitable against the Boers in S. Africa. A short time ago we were satisfied with two classes—"normal warfare" and "savage warfare"; that is to say, war against highly trained, well-equipped professional armies or against primitive races, of which every able-bodied man was an ill-equipped untrained soldier. Those distinctions no longer suffice. Here there is an initial difficulty, for in trying to imagine the tactics of the future we must first imagine the conditions under which war will be fought. Will they resemble the conditions of France and Flanders, of Macedonia, Mesopotamia or Palestine?

Conditions for Future Wars—One thing is certain, that the wit of man cannot devise a system which will be equally suitable for all. Principles there are, but nothing more. This is especially a British difficulty, for no army of the world is called upon to fight under such varying conditions as is the British, moreover, the British army of modern history has never fought in its own country. It is only necessary to reflect upon the history of the World War of 1914-8 to realize that, while Germans fought almost entirely on their own frontiers, if not in Germany, Frenchmen in France, Italians in Italy, Turks and Bulgarians in Turkey and Bulgaria, the British army and troops from the British Dominions and India fought all over the world. French troops, it is true, fought in many distant campaigns, but except at Salonika the overseas campaigns were preponderantly British, and cannot be considered apart from the British Dominions and India. The only other countries at all in like position are America and Japan, with few extra-territorial commitments.

As a further branch of this same problem we must for a moment consider the troubles of organization and equipment which are inseparable from those of tactics. The French army exists for the defence of France, the Italian army for the defence of Italy. Defence, no doubt, includes offensive action, especially in the case of Germany, but how simple these tasks seem compared with that imposed upon Great Britain with all her world-wide interests. It is easy to see with what confidence the general staffs of continental European nations can address themselves to their well-defined problems, and how much more complex are the manifold problems of the British general staff. Others can fortify their frontiers. Not so Great Britain or her Dominions, who must always be prepared to fight overseas in some theatre of war which cannot be foreseen with any degree of confidence or certainty. That is one fundamental and special complication, as the result of which tactics, organization and even equipment must always, from a British point of view, be something of a compromise, ready and able to be adapted to special conditions on the actual outbreak of war.

Let us consider for a moment what is to be the future of trench warfare. Will future wars reproduce the conditions of 1914 which led up to it? Will it be the normal warfare of the future, or was it no more than a passing phenomenon? Is it

battle-field. Meanwhile Germany introduced her heavy field howitzer and England her long-range field gun. The probable effect of these new factors in war were weighed, discussed and fairly accurately foreseen. But surprise came elsewhere, for the factor which was neglected was the power of the railways to maintain in the field such armies as the world had never beheld, with what we can now see was only the natural corollary—field fortifications impregnable to the material which armies then possessed, and by their strength and extent rendering impossible both envelopment and penetration. The truth is that it is less difficult to find the correct answer to the questions which are asked by history, experience and such foresight as we possess, than to foretell and ask the really vital questions

III.—THE ART OF LEADERSHIP

So far we have dealt almost entirely with the mechanism of war, the tactics of 1914-8, and possible future developments. There remains the all-important subject of command, and the qualities which go to make a great commander—the human element—for without true leadership arms and equipment and even training will achieve but little. "With a great general no action is executed which is the fruit of chance or fortune, everything is the result of combination and talent" (Napoleon's War Maxims, No. 82). Such was the considered opinion of the great master of war, and it can be confidently asserted that nothing has happened since he fought his last, and perhaps his most wonderful, campaign in 1815 to shake it. Surely no commander ever took greater risks than did Napoleon in the series of operations which ended at Waterloo, but they were the result of careful study and calculation and they came near to victory over almost double his numbers. Even now who can say what might have happened but for failure of his physical power and energy at the most critical moments, for surely England and Europe were never in greater danger than during the forty-eight hours after the Prussians had been beaten on the field of Ligny. How curious to reflect that a little more than a hundred years later the descendants of those who stood at Waterloo should have fought out another campaign on a vastly greater scale but on very similar lines and on ground not very far distant. The combatants were differently grouped, it is true, but the German blow in March 1918 was directed at the junction of the Allied armies, this time the British and the French, just as in 1815 the French blow was struck at the junction between Wellington and Blücher. Once again the British army was based on northern ports, while her ally was based on inland territory, once more the allies were for a time in danger of retiring along divergent lines and perhaps of defeat in detail. Numbers and weapons were different from those of 1815, but the main features of the campaign and the principles upon which it was fought out were the same. So true it is that the principles of war are simple and eternal, but the application of them varies in each particular case. Never yet has there been a great commander who has not read and thought deeply about his art in order that, by training his instinct on the right lines, he may decide correctly when the supreme hour arrives. It is not in order that we may master the principles of war that Napoleon has advised us to "read and reread the campaigns of Alexander, Hannibal, Gustavus, Turenne, Eugène and Frederick," but in order that we may "obtain the secrets of the art of war," and those secrets lie in application.

How strange, too, that of the great names which will go down to history in connexion with the campaign of 1918 two at least are those of men who had seen little or nothing of war before 1914—Foch and Ludendorff. For more than forty years Foch had no experience of anything but peace soldiering; Ludendorff heard an enemy's rifles and saw his own men drop for the first time in his life near Visé on Aug. 4, 1914. Both had mastered every detail of their art, not in the open field but in the solitude of the study. Each in his own way was an artist, but of the two it was Foch who had the inspiration, "the fire in his belly," which is the sign of the true master. Yet it is not enough to follow the movements even of these two, for all wars will not be

fought either with the numbers or the weapons of 1918 any more than with the weapons and over the extent of ground of 1815. Something between the two may be found to be nearer to the normal, but when due allowance is made for later invention, surely no campaign is better worth studying than this of 1815. Fought out between two great captains in the space of a few days and over a few miles of country, it forms a very epitome of war in all its branches. The doubt up to the last moment as to Napoleon's intentions, the strategical surprise; a concentrated force with one line of communication operating between two forces with divergent lines; the handling of D'Erlon's force and the attempt to effect a concentration on the battle-field at Ligny, the British and Belgian rearguard action at Quatre Bras and the retreat to Waterloo; Wellington's masterly disposition of troops as contrasted with Blücher's two days earlier, his telling use of advance posts, Hougomont and La Haye Sainte, breaking up Napoleon's massed attacks, the concentration of forces on the field and the great counter-stroke against Napoleon's right and rear, so largely the result of Blücher's loyalty and force of character; finally the stupendous defeat, the inevitable result of this most difficult manœuvre when successfully accomplished, as it was here, at Königgrätz and on one or two other occasions in history, and the relentless pursuit. They were indeed crowded days of glory. And then Wellington's characteristic comment "A damned serious business Blücher and I have lost 30,000 men. It has been a damned nice thing, the nearest run thing you ever saw in your life . . . By God! I don't think it would have done if I had not been there!"

Since those days Moltke has perfected the art of marching to the battle-field, of concentration by many different roads upon a single objective, and we have seen the same manœuvre developed under more difficult circumstances at Liao-yang. Arising from Moltke's tactics, so closely followed by Oyama in Manchuria, there have been many fierce disputes upon the comparative virtues of envelopment and penetration on the battle-field. Yet all these theories, these varying systems and bitter discussions, are based upon one solid foundation, the development of fire; for from the days of the long-bow to those of the modern tank it is to the development of fire that all changes in tactics are directly due. To-day, more than ever before, the power of developing fire is in the hands of the commander who seizes and retains the initiative. This he may do either through superior readiness for war and quicker mobilization, through a better strategical plan, or through superior numbers. In any case he will require superiority in the air, and better, more numerous or more skilfully handled covering troops, cavalry and rapid tanks. Decisive battle will be the object, and the experience of the World War would appear to prove that quick decision can only be obtained through envelopment. Converging lines of communication drawn from widely separated bases may then be a positive advantage, especially since the rapid means of communication now available have overcome much of their danger. Moreover, so devastating is the effect of converging or enfilade fire from modern weapons that the troops exposed to it are in deadly danger. An attacking force, it is true, may conceal an exposed flank by the skilful use of smoke, but not so the defending force, and the increased range and rapidity of modern arms are on the side of the attack rather than of the defence. Each commander will, therefore, strive with all his energy and will power to secure the initiative at the outset of a campaign, every artifice will be used and every engine will be employed. Sooner or later, however, one or other of the combatants will be forced to the defensive, but, if he is master of his art he will not resign himself to his fate any more than did Wellington and Blücher in 1815 or Joffre in 1914. He will devote all his skill and resource to recovering his freedom of action and to assuming that domination over events which will enable him, in his turn, to impose his will upon his adversary.

This change of fortune can only be brought about by a tactical counter-stroke, exactly as was done by the Entente armies in

¹ *The Crevy Papers*, vol. 1, chap. x

the methods resulting from these conditions, and the results achieved. Utterly dissimilar as were these two theatres of war, the underlying principles of victory are found, as always, to be the same. A firm faith in the offensive, concentration at the right time and against a suitable objective, surprise, and coöperation. The welding of all the forces, moral and physical, by the genius of the commander into one homogeneous whole, with one common inspiration, and directed to a common objective, namely victory. So far the two campaigns selected for illustration are in agreement with one another and with all the campaigns of the past, in every other respect the contrast is complete. On the one hand, in France and Flanders we find whole nations in arms, troops numbered by hundreds of thousands, and, as a necessary corollary, continuous lines, heavily fortified and without flanks to be turned, almost (one might say) without any vital line of communications, so complete were the railway and road systems available. As the result—long periods of stagnation, infantry deriving no assistance from the mounted troops (except indeed when acting dismounted), and dependent in the first place upon artillery and latterly upon tanks as well. Movement, when at last it comes, is by slow stages, until when victory is won it is by the crushing of a nation rather than of the armies in the field alone; for this was national war. On the other hand, in Palestine we find armies operating in a neutral arena, small in numbers with open flanks to the east, and each dependent upon a single line of railway, scope and objective not only for trained and disciplined mounted troops, making full use of their mobility, but also for light rapid-moving Arab levies harrying the Turkish communications, and achieving great strategical and tactical results, with but little loss to themselves, entirely by the power of movement. Artillery here plays but a secondary or even lesser rôle, for instead of congestion there is space—space in plenty, and when that element is present light troops come into their own; activity takes the place of force, and victory is over the field armies rather than over the civil population.

Between the two extremes of the western European front and Palestine lay such other campaigns as Mesopotamia and Macedonia, but these, though interesting enough in themselves, add nothing to our present purpose and seem only to emphasize the same theory in less convincing form—namely that each theatre of war, by its own distinctive physical features and climate, influences, if it does not actually dictate, the tactics by which battles and campaigns are won. Otherwise war might become an exact science instead of the most difficult of the arts.

This war of 1914-8, then, by its very size and variety, has solved no tactical problem, has answered none of the questions left by S. Africa in 1899-1902, or Manchuria in 1904-5, but, like all its predecessors, has raised many new ones. Strategy is still the art of bringing the enemy to battle on terms which are disadvantageous to him; tactics are still the methods employed for his destruction. In former wars this most desirable object was accomplished by a judicious combination of artillery, cavalry and infantry. To-day the object is the same, but the means have been complicated to a degree which in 1910 was altogether beyond human imagination. Railways have completed the work of Carnot and the French revolutionary generals, and made national war a complete reality; but through the perfections of the internal-combustion engine war itself has taken on a third dimension. If a great master was formerly required properly to handle and combine the comparatively primitive means at his disposal, how much greater should the artist now be who is to use, and not to waste, the much more complicated tools which science has now placed in his hands. As science advances the art becomes more complex, things tend to become greater than men, and use more difficult than invention. Always change has followed along the same line, but so rapid have been the latest steps that the armies of 1921 were further from those of 1821 than Napoleon's armies were from those of Hannibal; yet the human imagination and capacity remain as they were two thousand years ago.

All through the ages changes in tactics have been brought about by improvements in the means of killing. Latterly

science has advanced with giant strides, yet the mechanism of slaughter appears to be only in its infancy. How difficult, therefore, to foresee even with what weapons later wars may be fought, and what may be the next steps in tactical evolution. It is easy, indeed, to let the imagination run riot, and to picture whole populations destroyed by infernal machines easily and efficiently controlled by wireless waves. The pebble is to be thrown in at Berlin, Stockholm, Moscow or anywhere else you will, and the influence carried to the uttermost parts of the earth. Equally easy it is to persuade oneself that there will be no change, and the next war will begin exactly where the last left off. History teaches us, unfortunately, that neither of these views is likely to be exactly fulfilled. Possibly they serve as useful correctives one to the other; but the difficulty is to strike the happy medium. When so many new questions have been raised and so few old ones have been answered, only one definite new principle seems to have been established. It is that, more than ever before, tactical methods must vary in accordance with the theatre of operations, and that methods suitable to one country are unsuitable to another. Indeed even this is hardly new, since it is clear that methods which sufficed to overthrow the Mahdi at Omdurman would have been quite unsuitable against the Boers in S. Africa. A short time ago we were satisfied with two classes—"normal warfare" and "savage warfare"; that is to say, war against highly trained, well-equipped professional armies or against primitive races, of which every able-bodied man was an ill-equipped untrained soldier. Those distinctions no longer suffice. Here there is an initial difficulty, for in trying to imagine the tactics of the future we must first imagine the conditions under which war will be fought. Will they resemble the conditions of France and Flanders, of Macedonia, Mesopotamia or Palestine?

Conditions for Future Wars—One thing is certain, that the wit of man cannot devise a system which will be equally suitable for all. Principles there are, but nothing more. This is especially a British difficulty, for no army of the world is called upon to fight under such varying conditions as is the British, moreover, the British army of modern history has never fought in its own country. It is only necessary to reflect upon the history of the World War of 1914-8 to realize that, while Germans fought almost entirely on their own frontiers, if not in Germany, Frenchmen in France, Italians in Italy, Turks and Bulgarians in Turkey and Bulgaria, the British army and troops from the British Dominions and India fought all over the world. French troops, it is true, fought in many distant campaigns, but except at Salonika the overseas campaigns were preponderantly British, and cannot be considered apart from the British Dominions and India. The only other countries at all in like position are America and Japan, with few extra-territorial commitments.

As a further branch of this same problem we must for a moment consider the troubles of organization and equipment which are inseparable from those of tactics. The French army exists for the defence of France, the Italian army for the defence of Italy. Defence, no doubt, includes offensive action, especially in the case of Germany, but how simple these tasks seem compared with that imposed upon Great Britain with all her world-wide interests. It is easy to see with what confidence the general staffs of continental European nations can address themselves to their well-defined problems, and how much more complex are the manifold problems of the British general staff. Others can fortify their frontiers. Not so Great Britain or her Dominions, who must always be prepared to fight overseas in some theatre of war which cannot be foreseen with any degree of confidence or certainty. That is one fundamental and special complication, as the result of which tactics, organization and even equipment must always, from a British point of view, be something of a compromise, ready and able to be adapted to special conditions on the actual outbreak of war.

Let us consider for a moment what is to be the future of trench warfare. Will future wars reproduce the conditions of 1914 which led up to it? Will it be the normal warfare of the future, or was it no more than a passing phenomenon? Is it

work all would have appeared obvious and simple. That is the way of the artist; and the great tactician is a supreme artist.

(N M*)

TAFT, LORADO (1860–), American sculptor (see 26 354), was elected to the National Academy in 1911. He was director of the American Federation of Arts from 1914 to 1917 and in the latter year was appointed a member of the board of art advisers for the state of Illinois. He received a silver medal at the Panama-Pacific Exposition, San Francisco, 1915. His recent works include: "Black Hawk" (1912, figure of an American Indian, at Oregon, Ill.), Thatcher Memorial Fountain (1918, at Denver, Colo.), and "The Fountain of Time" (1920, at Chicago). In 1921 he published *Recent Tendencies in Sculpture*.

TAFT, WILLIAM HOWARD (1857–), 27th President of the United States (see 26 354), antagonized a considerable branch of his own party in 1911 by his endeavour, which proved unsuccessful, to secure a reciprocity agreement with Canada. Meanwhile wide public interest had been awakened in the conservation of national resources and the President's attitude was attacked by the conservationists. In 1909 Gifford Pinchot, chief forester, charged Richard A. Ballinger, Secretary of the Interior, with being opposed to conservation. A Congressional committee, after investigation, exonerated the Secretary, but he later resigned. The attack upon Ballinger was denounced by the President, who continued to be criticized in connexion with the sale of public lands, and who dismissed Pinchot from office. The President lost ground also as a result of a breach of friendship between himself and Theodore Roosevelt, who supported Pinchot. In 1912 the President signed the Panama Tolls bill, exempting American coastwise shipping from tolls, he affirmed that it did not violate the Hay-Pauncefote Treaty, and believed also that the United States had the right to fortify the canal. At the same time he expressed a readiness to arbitrate the question with Great Britain, who had protested. Cleavage within his party was crystallized at the Republican National Convention in 1912. In the pre-convention campaign Roosevelt came forward as leader of the progressive wing against Taft as leader of the conservative or "stand-pat" wing, and the mutual recriminations were bitter. At the convention, however, the conservatives controlled the party machine, and the committee on credentials by arbitrary decisions excluded most of Roosevelt's contesting delegates. Taft was renominated on the first ballot, receiving 561 votes, 21 more than the required majority. Roosevelt denounced the action of the convention and later was nominated by the newly formed National Progressive party. In the ensuing election Woodrow Wilson, the Democratic nominee, won an overwhelming victory, securing 435 electoral votes to 88 for Roosevelt and 8 for Taft. President Taft carried only two states, Utah and Vermont, and those only by small pluralities. The general feeling throughout the country was that President Taft had shown a deplorable lack of administrative firmness, his good nature having caused him to vacillate. On retiring from the presidency in 1913 he became Kent professor of law at Yale, but devoted much time to lecture engagements. In 1913 he was elected president of the American Bar Association, and in 1914 first president of the American Institute of Jurisprudence, organized to improve law and its administration. After the outbreak of the World War in 1914 he supported President Wilson's strong stand for neutrality. In 1915 he approved the Army League's campaign for preparedness. He was an active promoter of the League to Enforce Peace, but after America's entrance into the war he argued that victory was necessary for attaining lasting peace. In 1918 he was appointed by the President a member of the National War Labor Board for arbitrating labour disputes during the war. In 1919 he endorsed the Peace Treaty of Versailles, regarding its most important part to be the Covenant of the League of Nations. He spoke throughout the country in behalf of the League. After the Senate's rejection of the Peace Treaty he urged reservations if these would secure ratification. In July 1920 he was appointed to represent the Grand Trunk railway on the board of arbitration for determining the sum to be paid by the Dominion of Canada

when the road was to be made a part of the national system. He supported Warren G. Harding, the Republican candidate for president in 1920. On June 30 1921 he was appointed by President Harding Chief Justice of the Supreme Court to succeed Edward Douglas White, deceased.

He was the author of *Popular Government, its Essence, its Performance, and its Perils* (1913); *The Anti-Trust Act and the Supreme Court* (1914); *The United States and Peace* (1915), *Ethics in Service* (1915, Yale lectures); *Our Chief Magistrate and his Powers* (1916, Columbia lectures) and *The Presidency: its Duties, its Powers, its Opportunities and its Limitations* (1916, lectures at the university of Virginia).

TAGORE, RABINDRANATH (1861–), Indian poet and author, was a member of a well-known Bengali family noted for its activities in literature, art and religious reform as well as for its public benefactions. In 1921 the head of the orthodox Hindu branch was Maharaja Bahadur Sir Prodyot Coomarr Tagore (b. 1873), a great-nephew of Prosunno Coomarr, who was the first Indian to be nominated to the Viceroy's Legislative Council and founded the Tagore law professorship in the university of Calcutta. The grandfather of Rabindranath was Dwarkanath, "merchant, philanthropist and reformer," who was known to his contemporaries as "Prince Tagore." He visited England in 1842 and again in 1845, sat to D'Orsay for his portrait, and, dying of fever in London in 1846, was buried at Kensal Green. In conjunction with Raja Rammohan Roy he initiated the movement of religious reform which took shape as the Adi Brahma Somaj. This work was continued by his son Maharshi Devendranath, of whose seven sons, Dwijendranath, the eldest, devoted himself to the study of philosophy, Satyendranath, the second, was the first Indian to enter the covenanted civil service and served for 35 years in the Bombay Presidency, and Jyotirendranath, the third, was an accomplished musician. Their cousins, Abanindranath (b. 1871), Gogonendranath and Narendranath, became distinguished artists. Rabindranath, the youngest son, was sent to England to study law, but soon returned. In 1901 he established the famous Shantiniketan, or abode of peace, at Bolpur, a village 93 m. from Calcutta. Originally organized as an *ashram*, or retreat, by the Maharshi, it was developed by Rabindranath into a school conducted on unconventional lines, and he aimed at enlarging it into an international university which should comprehend the whole range of eastern culture. His outlook upon the west was thus summarized by him in a letter published in the Indian press at the close of 1919. "The bulk of English people can never be in a normal state of mind with regard to us, our situation being unnatural, and I am impelled to think that it is best for us to do our own work quietly in our own surroundings." Gandhi's policy of non-cooperation was, however, severely condemned by him as perverted nationalism, "which was making of India a prison," in a letter addressed to the principal of his school at Bolpur in June 1921. He paid frequent visits to Europe, Japan and the United States (where his son Rathindranath became a student in the university of California), and carried through several lecturing tours. His reputation as a writer among his own countrymen was early assured, and the 30 poetical and 28 prose works composed by him in Bengali are now regarded as classics. The English public first became interested in his works in 1912, and his fame rapidly spread. In 1913 he was awarded the Nobel Prize for literature and utilized the whole amount, £8,000, for the upkeep of the school at Bolpur. He was given the degree of Doctor of Letters in the university of Calcutta and accepted a knighthood in 1915, but addressed a letter to the Viceroy in 1920, resigning the title as a protest against the methods adopted for the repression of disturbances in the Punjab.

His more important books, of which English translations have been published, are the poems *Gitanjali* (Song Offerings) (1913), *The Crescent Moon* (1913), *The Gardener* (1913), *Songs of Kabir* (1915), *Fruit Gathering* (1916), *Stray Birds* (1917), *The Lover's Gift and the Crossing* (1918); the plays *Chitra* (1914), *The King of the Dark Chamber* (1914), *The Post Office* (1914), *The Cycle of Spring* (1917), *Sacrifice* (1917), and other plays, the novels, *The Home and the World* (1919), *The Wreck* (1921), as well as a volume of letters, *Glimpses of Bengal* (1921), and the short stories *Hungry Stones*

TANGANYIKA TERRITORY

(1916) and *Mushi* (1918); and republished lectures, *Sadhana, or the Realization of Life* (1913), *Nationalism* (1917), *Personality* (1917). He also published his *Reminiscences* (1917). See W. W. Pearson, *Shantimoksha* (1917); article in *Hindustanee Students* (March 14 1921).

TANGANYIKA TERRITORY, the name officially given in Jan. 1920 to that part of ex-German East Africa administered by Great Britain. It has an area of some 365,000 sq. m., compared with the 385,000 sq. m. of the former German protectorate, the rest of the region having been added to Belgian Congo except the small Kionga district at the mouth of the Rovuma, which was incorporated in Portuguese East Africa. Urundi and Ruanda, the provinces acquired by Belgium, were the most populous parts of German East Africa, and whereas the population of the German protectorate in 1916 was estimated at some 8,000,000 that of Tanganyika Territory in 1920 was under 5,000,000. Europeans in 1920 numbered about 1,400, of whom 1,400 were British and 300 Greek. The largest towns were Dar es Salaam (20,000 inhabitants) and Tanga (16,000) on the coast, and Tabora (25,000) inland.

With the conquest of the country in 1917, British administrators were appointed by the British and Belgians in the territories they occupied, Mr. (afterwards Sir) H. A. Byatt being chosen by

the British. His headquarters were at Dar es Salaam. Iringa, Mahenge and other regions were, until March 1918, administered by Gen. Northey's chief political officer, Mr. (afterwards Sir) H. L. Duff. At first the Belgians, with Col. Malfeyt as Royal Commissioner, administered, from Tabora, the western area from Victoria Nyanza to near the southern end of Tanganyika. In March 1918 the Tabora region was taken over by the British. By decision of the Supreme Council in May 1919 the mandate for German East Africa was assigned, without qualification, to Great Britain, but Belgium advanced claims to retain not only Urundi and Ruanda but a much larger area, including the province of Ujiji, with the lake terminus of the railway from Dar es Salaam. The matter was settled by an Anglo-Belgian agreement signed in Sept. 1919. By this agreement Ujiji province went to Great Britain, and also such parts of Urundi and Ruanda as were needed to allow the projected railway from Tabora to Western Uganda—a link in the Cape to Cairo scheme—to remain in British administered territory. By another convention signed in March 1921 Belgium obtained the right of transit of goods free of all custom duties over the railway from Kigoma (the lake terminus of the line) to Dar es Salaam, and in general by any other route adapted for transit,

together with areas (on payment of nominal rent) at both ports for wharfs, bonded warehouses, etc. The districts which Belgium had temporarily administered but which fell within the British mandatory area were formally transferred to the British administration on March 22 1921.

Orders in Council for the government of Tanganyika Territory were made in July 1920. The next month the administrator, Sir Horace Byatt, was gazetted governor and Sir William M. Carter appointed Chief Justice. The terms of the mandate, as proposed by Britain, were made public in March 1921.

In accordance with the terms of the Covenant of the League of Nations the mandatory was bound to allow equality to nationals of all members of the League in matters of residence, trade and commerce. This condition had an important bearing on the position of British Indians in the territory. It prevented any discrimination being made against them, as had been done in the neighbouring colony of Kenya. A proposal had been made during the World War that the territory should become, in effect, a reserve for India. This proposal could not be adopted, but in Aug. 1919 the Colonial Office consulted the Indian Government as to the desirability of setting aside special areas for colonization by Indians. Investigations were made in the territory by Sir Benjamin Robertson, with the result that the Government of India in a despatch dated Feb. 10 1921 stated that it was improbable that Indian farmers would be attracted to Tanganyika, where only large estates seemed likely to succeed.

The Indian Government moreover drew attention to the rights Indians possessed under the mandate and urged that Indians should also be granted perfect political equality with other settlers, of whatever nationality. Indians in Tanganyika numbered in 1921 some 15,000. They had penetrated to every part of the territory, and save for the competition of Greeks in certain areas practically monopolized the retail trade.

The transition period—1918–21—proved difficult, and there was much delay in setting up the new machinery of government. This was in part inevitable, as until the Treaty of Versailles came into force, an event delayed until Jan. 20 1920, the country was still legally German territory. The whole of the German settlers were repatriated and their estates sold during 1921. Until this process was completed no new land grants were made, and agriculture was practically at a standstill. A Land and Mines Department was, however, formed towards the close of 1920, and mining regulations were promulgated early in 1921. The only mineral worked on a considerable scale was mica, the chief deposits being in the Uluguru mountains. Between 1917 and 1920 mica valued at £40,000 was exported for the British Ministry of Munitions. In March 1920 the mines were closed. The alleged indifference of the administration to the needs of the commercial and planting community evoked strong protests, and further difficulties were caused by the change from the German currency in rupees at 15 to the £ to the florin at 10 to the £, preliminary to the substitution of the shilling for the rupee, as in Kenya (see KENYA COLONY). The exports and imports for 1917–20, taking the rupee at 15 to the £, were:—

	Imports	Domestic Exports	Re-exports
1917–8	£1,109,000	£591,000	£36,200
1918–9	£1,007,000	£674,000	£26,200
1919–20	£1,158,000	£1,330,000	£96,300

These figures did not include sisal and cotton to the value of £284,000 exported by the custodian of enemy property nor the mica exported for the Ministry of Munitions. The principal exports were sisal, cotton, hides, skins, copra, coffee and ghee. Up to 1920 the exports were mainly accumulated stocks. The chief imports were cotton piece goods, rice and other foodstuffs. The re-exports represented transit trade with the Belgian Congo. Trade was mainly with Zanzibar, Kenya and India. For the year ending March 31 1920 the net tonnage of the ships cleared was 193,000 (154,000 British).

Sir Horace Byatt and his staff had a difficult task in building up a new administration on the ruins of the German system. In native affairs they sought to reestablish the old tribal organization, almost destroyed under German rule, and steps were taken to abolish slavery. During 1918 and 1919 the Government had to feed large numbers of the people, who, as a result of continued drought, suffered severely from famine. The Indian penal codes were introduced, but it was not until 1921 that civil courts having jurisdiction over non-natives were established. The absence of such courts was not an unmixed evil in this period of transition, though traders, who could

not sue for debts, were loud in complaints. But the tendency to wild speculation and to charge high rates of interest was checked. Customs laws—with a general *ad valorem* duty of 10% on imports—similar to those in force in Kenya were introduced before the World War ended, and, in 1921, British weights and measures. Revenue was derived chiefly from the customs dues, trade taxes and licences, and hut and poll taxes, each able-bodied male native paying not fewer than three florins a year. While revenue naturally rose as the area under civil administration increased, so likewise did expenditure. Up to March 31 1920 the total revenue received was £1,596,000, and the total expenditure £1,365,000. It then became necessary to spend much larger sums to put the country into working order, and for the year ending March 31 1921 the Imperial exchequer made a grant of £330,000. For the next financial year the Imperial exchequer made a grant of £914,000—the Colonial Office had asked for £1,500,000. Heavy expense was incurred in making good the damage done during the World War to railways, roads and harbours. The garrison maintained three battalions of the King's African Rifles, cost about £250,000 yearly.

Under British administration the German names given to certain districts and towns were replaced by native names. The following changes were made: Wilhelmstal district became Usumbura district and Wilhelmstal (town) Lushoto. Bismarckburg district became Ufipa and Bismarckburg (town) Kasanga. Langenburg district became Rungwe and Neu Langenburg (town) Ntukumu. Wiedhafen, on Lake Nyasa, became Mlanda. In 1917 Oldoinyo Lengai (God's mountain) at the S. end of Lake Natron was in frequent eruption, it is the only known active volcano in the territory. In May and June 1919 very severe earthquakes occurred in the S.W. part of the territory. By the fall of the side of a mountain near the N.E. end of Lake Nyasa some 5,000,000 tons of earth and rocks were displaced—the falls in the Livingstone mountains altered considerably the face of the country.

See *Report on Tanganyika Territory* (1921), a valuable official monograph covering the period to the end of 1920; the *Colonial Office List* for parliamentary papers, A. S. and C. G. Brown, *The South and East African Year Book and Guide* (London, annually), Hans Meyer, *Ostafrika* (1914); F. S. Jocelyn, *The Tanganyika Territory* (1921), and the authorities cited under GERMAN EAST AFRICA. (F. R. C.)

TANKS.—The name "Tank," applied during the World War to a bullet-proof, armed, track-driven, climbing, automobile, machine-gun destroyer, was first given to an engine of war in Dec. 1915, as a blind to conceal the true nature of the experimental fighting machine then being secretly constructed in England. After the first appearance of the machine in the field in Sept. 1916, the word was universally adopted. It is here used to describe all armed and armoured automobiles of a fighting type propelled on the caterpillar system. To the British is due the credit of first conceiving and introducing this weapon, which was destined to exert a decisive influence on the course of the war on land.

The conditions responsible for the birth of the tank were not in principle new. They were the same as have always existed in war, but intensified by the application of modern methods to the situation unexpectedly created by the course of the land campaign on the western front. Neither the strategic development nor the outcome of its full tactical exploitation had been foreseen. It was owing to this that so vital a factor as the tank proved to be should have had to be improvised during the course of hostilities as the solution of an age-old problem. The problem was that of giving effective assistance, in the shape of direct protection, to infantry advancing under fire.

Apart from cooperation elsewhere, assistance can be given in two ways. It can be effected either by artillery, which with its power of long range action can support advancing infantrymen whilst in motion, and therefore unable to make full use of their rifles, by shooting over their heads, or more directly by the provision of some form of physical protection against blows or missiles. The attempt to provide protection whilst retaining the power of movement both for hand-to-hand fighting and also against missiles, as opposed to that afforded by fortification to troops when stationary, has recurred throughout the history of warfare. The best known examples of it are the shield and body armour carried or worn by the man. Though the need for these did not then cease, their practicability was terminated by the introduction of firearms, since no weight of material that the human being or the horse could carry was of avail against missiles propelled by the force of powder. There was

also the idea of giving wheel-borne collective protection to several men at a time, and devices for doing this have been numerous, and have varied according to the progress of mechanical knowledge and the resources available at the moment.

The Assyrians made use of war chariots, or mobile fortresses, which were adopted from them by the Egyptians and Israelites.¹ Chariots were also employed by the Chinese in 1200 B.C. Then, for siege warfare, there were the Roman *Testudo*, or "Tortoise," and the mediæval *Beaufroi*, or "Belfry," which was usually assisted by the "Cat" or "Sow," an engine of a more mobile type. About 1400 A.D. Conrad Kyeser wrote on this subject, and some 20 years later Fontana and Archinger designed cars, the latter a large machine to carry 100 men. In the middle of the 15th century appeared the "Scottish War Carts," known also as "Tudor War Carts." In 1472 one Valturio designed a machine to be propelled by wind sails. In 1482 Leonardo da Vinci wrote to Ludovico Sforza describing a machine which, except in motive power, was in essentials the counterpart of the tank. A battle car was designed for the Emperor Maximilian I., and in 1558 Holzschuher described one for use with infantry and cavalry. Eleven years later two land battleships are stated to have been built by Simon Stevin for the Prince of Orange. Except those propelled by the wind, all the above were moved by the muscular power of men or horses. In 1634 David Ramsey took out an English patent for a self-moving car, and Caspar Schott designed one for use against the Turks. In 1769 Cugnot, a Frenchman, actually constructed a steam-driven road car which could be used in war; and later Napoleon wrote a paper on the subject of the automobile in war. In 1855 James Cowan, in England took out provisional protection for a "locomotive battery fitted with scythes to mow down infantry," and endeavoured to persuade Lord Palmerston to take up this adaptation of the chariot. Capt Nadar put forward a similar suggestion in 1870; and in 1900 John Fowler, of Leeds, produced armoured steam traction engines for S. Africa.

The introduction of rifled breech-loading firearms did not force into use any system of man-borne or horse-borne protection, notwithstanding that the range, volume and accuracy of all kinds of fire was immensely increased and its effect rendered correspondingly more deadly. For, it was less possible than it had been to produce shields or body armour which were capable of resisting the greater penetration of the rifle bullet and yet light enough to be carried, whilst no practical method of mechanical propulsion across country of the heavy weights involved in collective protection had been discovered. And yet, as time passed, the need for some more intimate form of help for the infantry soldier than that afforded by artillery grew more insistent. It was accentuated by the invention of the machine-gun and of the magazine and the automatic rifle, and by every successive improvement in small arms or artillery. In point of fact, however, the mechanical difficulties had been overcome some years before 1914. The "caterpillar," or "track," or "endless band" system of propulsion, by which weight is distributed by the increase of the surface bearing on the earth, instead of being concentrated, as with a wheel, and a better tractive effect obtained, which had been known, and in the United States largely employed, for some years, had furnished the key to cross-country mobility, and the perfecting of the internal combustion engine had subsequently given to the world compact power with light weight.

The principle of the "footed wheel," "caterpillar," or "track" system of propulsion appears to have originated in the patent of Richard Lovell Edgeworth in 1770 for a device whereby a portable railway could be attached to a wheeled carriage.² This employed the basic principle of all subsequent track-driven machines. Then followed patents for tracks of different natures, by Thomas German in 1801, William Palmer in 1812, John Richard Barry in 1821. In 1846 there was the Boydell engine, with footed wheels, improved upon by Andrew Dunlop in 1861, whilst in 1882 Guillaume Fender and John Newburn designed modifications of tracks. In the following year the actual use of tank-like engines for war was predicted by M. Albert Robida in *La Caricature*.³ In 1886 there came the Applegarth tractor, and the Batter tractor was patented in the United States two years later. The latter anticipated the tank in many details. All the above machines were steam propelled. In America steam locomotives with caterpillar tracks, some furnished with sleds

or runners, had for years before the war been applied to haulage in lumber camps. After the appearance of the petrol engine Frank Bramond patented in 1900 a special form of track for pneumatic tired wheels. In 1907 a Rochet-Schneider car fitted with a chain track was tried for military traction purposes, and in 1908 a 70 H.P. Hornsby-Ackroyd chain track tractor took part in a review at Aldershot, and Hornsby also demonstrated a 75 H.P. Mercedes motor car fitted with tracks, a speed of 20 m. an hour being attained on sand. Another British tractor, of the footed wheel type, was the Diplock Pedrail. In America petrol-driven caterpillar tractors had before the war become quite common for agricultural purposes, amongst them being the Bullock, Killen Strait and Holt tractors.

While experiments in petrol-driven caterpillar-track tractors for military use had been carried out by the British authorities before the war, there had been no serious investigation or proposal by any nation to develop the caterpillar principle for fighting as opposed to transport purposes. In 1903 Mr. H. G. Wells had in fiction anticipated the intervention in battle of fighting machines which amounted to large-size tanks. Five years later Capt. T. G. Tulloch had suggested a scheme for a steam-driven pedrail armed and armoured trench-crossing machine, and in 1911 had put forward a proposal to use armed and armoured linked Hornsby-Ackroyd tractors with a crew of a hundred men. And in 1912 Mr. L. E. de Mole, an Australian, actually placed before the War Office a design, followed in 1916 by a model, for a climbing, fighting track-driven machine. This was the real prototype of the tank, and in some particulars, especially its pivoted ends and flexible chain tracks for steering a curved course, it seems to have been superior to the machine actually produced. Unfortunately, whatever may have been official opinions or intentions in regard to this scheme, no action was taken.⁴ In Dec. 1915 a caterpillar-track wire-cutter, invented by M. J. L. Breton, the French deputy, and called the *Tracteur-porte-cisaille*, or *Tracteur Breton*, was tried, and orders were given for a few, which, however, were not constructed. The *Boirault* cross-country motor, which consisted of an articulated polygon, was also tried, but was found impracticable owing to lack of steering power.

In the years preceding 1914, military opinion generally inclined to the belief that in any future struggle open warfare, or a "war of movement," alone was probable, that in such a campaign mobility was the essential; and that there would not be many occasions when a sheer unassisted frontal attack would have to be pressed to the end against carefully prepared positions held by unshaken defenders. It was appreciated that such operations if attempted would be costly to the infantry, though how costly was not realized. And it was thought that they could usually be avoided by manoeuvre, or, if they had to be carried out, would be assisted by envelopment or flank action which would relieve the task of the infantry by weakening the power or determination of the defence to fight to the end, or by operating at night or by surprise. The other, local, measures for assisting the infantry consisted of the bombardment and supporting fire of the attacking artillery up to the moment of actual assault, and the covering rifle fire from stationary infantry to cover those who could not use their rifles whilst actually moving forward, both of which were intended to keep down the defenders' fire. Great and, as it proved, undue reliance was placed on this concentration of the fire-power of the attack both from artillery and from small arms. It was hoped that by the continual cumulative reinforcement of the firing line until it had arrived at assaulting distance, and possibly dug itself in, a superiority of fire over the defenders would be gained sufficient to permit of the delivery—helped by artillery till the last moment—of the final assault with the bayonet. To enable the firing line to improvise some sort of protection when it could no longer move forward and was "frozen" to the ground, the infantry of all armies were equipped with a portable entrenching tool. The blade of this instrument, it was thought, also, might in some cases serve as a species of shield. Except by the Ger-

¹ The greater part of this historical summary is taken from *Tanks in the Great War* by Brvt.-Col. J. F. C. Fuller, and *The Forerunner of the Tank* by H. M. Manchester, *The American Mechanist*, Vol. xlix. No. 15.

³ *Strand Magazine*, June 1917.

⁴ Mr. de Mole's ideas had no influence on the evolution of the tank, for the originators of the latter were ignorant of his project, which only became generally known after the war, in Oct. 1919, some four years after the Mark I tank was designed, when the subject came up before the Royal Commission on Awards to Inventors.

mans, wide extension of the attacking infantry was relied on to reduce the casualties. The Germans favoured mass tactics, trusting to break through by weight of numbers in spite of loss.

Up to the outbreak of the war, therefore, partly owing to a wrong estimate of possibilities; to a non-appreciation of the progress of science in its application to warfare, to fallacious reasoning based thereon; to the necessity for economy in military matters, and to the mechanical difficulties which had so long stood in the way and which were still thought to stand in the way, not only had no solution of the problem of providing mobile protection been arrived at, but no serious effort to reach a solution had for a long period been attempted. It followed that when hostilities opened in 1914, save for the development of artillery tactics and materiel, not one of the combatants was really in possession of better means of rendering possible the advance of infantry under fire than those which had been at the disposal of the opposing forces in the Russo-Japanese War of 1904-5. Indeed, in face of the actual growth in strength of the tactical defensive all armies were in this direction relatively weaker than in previous wars of modern days. And the weakness seems to have caused no anxiety. The prevailing complacency, however, was soon to receive a rude awakening.

It might be imagined, since the Germans first assumed the offensive on the western front, that they would have been the first to become aware of this deficiency and to feel the need for mobile protection. This was not so. Though they carried out a succession of attacks during the first month of the war they were not held up, except for a short time before the fortresses Liège, Namur, Maubeuge, and Antwerp, which they reduced by gunfire, and were able until they reached the Marne to continue their onward rush and to maintain their pressure. These attacks, with the exception of the abortive assault on Liège, were not executed against carefully prepared positions such as developed later, and were not usually of a purely frontal nature unassisted by tactical or threatened strategic flank operations or envelopment. Nevertheless, the German losses were extremely heavy, probably more severe than had been expected, but were thought to be the price of the apparent general success of their strategy at the time. They would have been truly justified had the German plan of campaign in fact succeeded. During this period such losses as they suffered were caused mostly by the quick-firing field artillery of the French on the one hand, and on the other by the musketry of the highly trained long-service British infantry hastily entrenched in improvised positions. This, it is stated, was so intense as to lead to the erroneous conclusion that the British Expeditionary Force had been secretly and lavishly equipped with machine-guns. And it was not owing to the strength of the resistance of the British or French field armies on the defensive that the progress of the Germans was finally brought to a standstill at the Marne.

It was only when the rôles of the two sides were reversed and the Allies assumed the offensive that the factors first came into play that eventually forced on them a fresh effort to solve the ancient problem. It was then, so far as the British were concerned, that it became apparent that, notwithstanding the weakness shown by permanent forts which had quickly succumbed to the power of specially designed ordnance, not only had the capacity for passive resistance of field defences been much increased, but the active power of the defensive had been very greatly enhanced by the application of modern methods and the scientific employment of modern arms.

More than a hint of this was given first by the nature of the resistance made by the German rear-guards during the battle of the Marne, notably at the crossing of that river at La Ferté-sous-Jouarre on Sept. 9, where the British 4th Div. was held up almost entirely by machine-gun fire in its endeavour to force the passage. It has since become known that the Germans had concentrated at this spot some 42 machine-guns, equivalent to the number of these weapons with 21 British battalions.¹ Later, during the fighting on the Aisne, greatly as the British were harassed by the German weight of artillery, it was mostly by machine-guns that their efforts to advance were checked, in some instances by the combined action of these

guns and obstacles, such as abatis and wire entanglements, which though improvised, were found to be very effective, especially in view of the British weakness in artillery. Even at this early stage so strong were the German defences that the nature of the operations began to approximate to that of siege warfare. Later, at the beginning of Oct., in the more open action when the British endeavoured to outflank the German right to the north of Lille it was the same story. Their progress was in every direction opposed by machine-guns, sometimes in the open, sometimes in defended villages or houses, and often protected by improvised entanglements. Almost invariably the presence of German advance troops even in small bodies implied the presence of machine-guns which were handled with the greatest skill. The static warfare which then ensued on the western front during the winter of 1914-5 after the failure of the German offensive and the efforts of both sides to outflank each other on the coast, only accentuated the tendencies already noted. Its effect was to convert the struggle into a species of "field siege" warfare from which all possibility of manœuvre was excluded and in which all efforts at the offensive had perforce to be attempts to break through, entailing frontal attacks. Nevertheless, though this development had been expected by the Germans no more than by the Allies, and their immense preparations had been based on their original plan of an overwhelming and short offensive campaign on this front, they were in many ways well equipped for it. They were for a long time in possession of an immensely preponderating artillery—an advantage in attack or defence; whilst in defence the nature of the fighting gave full scope to their untiring industry backed up by their genius for field fortification. They also had a great proportion of technical troops and an armament of machine-guns far superior to that of the Allies. Though the relative conditions between the sides in these particulars changed, in the struggle which lasted for nearly four years the defensive was for a long time to prove stronger than the offensive, all attempts at which had to be carried out without finesse, by the method of brute force with its prodigal loss of life. It was during this period more especially that the machine-gun was to exert its influence and to reveal to the full its true power in the prepared defensive.

The machine-gun was no new invention, but its possibilities when cleverly used in numbers, though shown to some extent in the Russo-Japanese War of 1904-5, had not been proved. The British and German were equipped with almost identical types of the same gun differing only in detail, both being the outcome of the genius of the late Sir Hiram Maxim.² Previous to the Russo-Japanese War the weapon had never been held in great esteem by the British military authorities, except by a few enthusiasts, but the lessons of that campaign had led to an effort to increase the proportion of these guns in the equipment of the army beyond that which existed at the time of the S. African War. But this was not done owing to mistaken ideas of economy. It was also held that superior musketry fire discipline would make up for any deficiency in this respect, and great pains were taken to train the infantry to attain a rate of fire which in fact did exceed that of any other troops. On the other hand the machine-gun had become the weapon *par excellence* of the Germans. They perhaps of all nations had most correctly gauged its worth, the fact that it combined the maximum of killing power with the minimum of vulnerability, and the economy in a military sense of its adoption on a large scale. And after the Russo-Japanese War they had made a specialty of it. Without ostentatiously increasing the proportion of machine-guns with their infantry formations they had armed special units with them and accumulated a large stock in reserve. They had also trained a body of picked officers and men in their technical and tactical use. Their army, therefore, entered the war in this particular better equipped than any other. The first sign of this fact was given by the bold method in which they employed machine-guns in their onrush in the west. The next, as has been said, was the skilful way in which they used them in defence, at first in rear-guard operations, and then in the prepared defensive. In these tactics they excelled, and specialized in combining the intense fire power of the machine-gun with the obstacle—usually barbed wire entanglements—in a way which had never before been done. So far from the weapon being looked upon as a rare article impossible of replacement to be cherished and kept out of danger, it was not considered a disgrace for a gun to be lost once it had earned its value in killing the enemy. This apparent prodigality was a measure of the

¹ "Die deutsche Kavallerie in Belgien und Frankreich," Von Poseck, p. 102.

² The British were equipped with the Vickers, the French with the Hotchkiss, and the Germans with the Vickers-Maxim.

reserve of weapons available and the chief source of the great increase revealed in the strength of the defensive. The pre-war policy of the Germans was justified in the event. It was the combination of this weapon with barbed wire as initiated by them that suggested the need for the tank. And it was its intensive application and elaboration after the opposing armies had crystallized in two continuous closely opposing lines of carefully entrenched positions extending from the sea to Switzerland, that eventually brought the tank into being.

BRITISH TANKS

Early in Oct. 1914, it was borne in on the mind of a British officer who had special opportunities for ascertaining what was actually occurring, that the frontal assault of prepared positions, especially when adequate artillery cooperation was not available, had become impossible unless some more effective assistance could be rendered to the infantry than that previously contemplated and accepted as adequate; that this assistance in the absence of gun power and ammunition sufficient to blast a way through the whole enemy system of defences—trenches, obstacles and machine-guns—should consist of some protected power-driven machine which could force itself through barbed wire, climb across trenches and destroy by gunfire or crush by its weight the machine-guns of the defence. Knowing of the existence and cross-country capabilities of the American Holt caterpillar tractor, it occurred to him that a specially designed machine developed on similar lines would be the solution of the problem. This officer, Lt.-Col. (later Maj.-Gen.) E. D. Swinton, R.E., at that time acting as official military correspondent ("Eye-witness") with the British Expeditionary Force, was the first officially to put forward a scheme for a caterpillar machine-gun destroyer, in a communication to the Secretary of the Committee of Imperial Defence in London on Oct. 20 1914.¹ Though the machine then contemplated and finally evolved was for the purpose of giving infantry protection when advancing, it was expressly designed to do this indirectly, by its own offensive and destructive action. It was definitely intended, and designed, for the express purpose of forcing its way through wire and crossing trenches and hunting for machine-guns in order to destroy them by shell fire or to crush them by passing over them. The only "protection"—using the word in its limited, and more usually accepted sense—afforded by it was that of its bullet-proof sides to its own fighting crew. This point is accentuated because of the misconceptions which have existed as to the rôle of the tank, chiefly as to its being an armoured vehicle for transporting men, or a mobile shield to give cover to those moving up behind it. It did in fact perform this latter service, but only incidentally, in its quest for machine-guns. Machines for carrying up bodies of infantry and stores were not actually developed until three years later as an extension of the principle. As will be seen, the necessity for finding some mechanical method of carrying troops under cover across country had already occurred independently to a French officer. And in England similar suggestions were put forward, also independently, by Lt. R. F. Macfie, in Aug., and Lt. B. J. F. Bentley in Oct. 1914.

The history of the tank from Oct. 1914, until it took the field 23 months later, and even afterwards, is a record of progress made often in the face of apathy, scepticism and even opposition. This is typical of the history of the evolution of most inventions or new ideas, but is somewhat remarkable in this instance because the subject was one of vital urgency immediately concerning the lives of the British troops in the field. It is also remarkable for another reason. The idea of this land weapon not only received its first help toward realization from the minister responsible for the navy, but its realization was, indeed, only rendered possible by the financial support given by him from naval funds. The gist of the suggestion made to the Secretary of the Committee of Imperial Defence in Oct. 1914 was put forward by him in a memorandum and reached the First Lord of the Admiralty, Mr. Winston Churchill, who was

predisposed towards experiments in the direction of some mechanical armoured device for carrying troops across country, to take the place of the armoured motor car which could only operate on roads. A certain number of these cars, belonging to the armoured car section of the Royal Naval Air Service, organized by the Admiralty, had been operating in France and Belgium, and their utility had become seriously curtailed by the destruction of the roads and the state of trench warfare which had arisen. In Jan. 1915, the First Lord, to whom the employment of mobile bullet-proof shields had already been suggested, took up the question of the urgent need for methods of meeting the deadlock reached on land, and his views were officially brought to the notice of the army authorities. He did not, however, only place the matter before the military. He caused researches to be made in the direction of crossing trenches by means of tractors carrying portable bridges, and in Feb. summoned a special Admiralty expert committee under the chairmanship of Mr. (later Sir) E. H. Tennyson d'Eyncourt, the Director of Naval Construction, to explore further the subject of mechanical cross-country transport generally. This committee at once started work and continued its labour for some time, experimenting chiefly in the direction of "landships" with large wheels, coupled steam rollers, pedrail and caterpillar tractors, single and articulated, for which suggestions had been put forward by different individuals. The underlying idea of all these investigations was the production of a machine for the conveyance of troops, not a machine-gun destroyer.

Previous to the receipt of the First Lord's views, the need of a specific machine-gun destroyer had been urged on the War Office directly by Col. Swinton early in Jan. 1915, followed by representations from Capt. Tulloch. The War Office took the matter up, but did not associate itself with outside technical experts to investigate possibilities, as had been recommended. After the trial and failure in Feb. of a Holt caterpillar tractor to cross obstacles which it was not designed to negotiate, and that of a wheeled tractor with the naval trench bridging device in May, it dropped the whole idea as impracticable. Meanwhile the Admiralty committee had continued its experiments, though without knowledge of the conditions of the military problems it was required to solve. In June, the War Office, then aware of the Admiralty's activities, became desirous of collaborating in them, and a joint naval and military committee was formed. The efforts of the Admiralty thus obtained the first official recognition of the service for whose benefit it was really working. At the end of the month the committee was furnished by the War Office with a detailed specification of the requirements of the destroyer as prepared by Col. Swinton and forwarded by the Commander-in-Chief in France, and the Admiralty designers were for the first time in a position to apply their inventive faculties to fulfilling certain definite conditions. The result of their efforts was the production in Jan. 1916 of an experimental machine paid for entirely from naval funds and produced almost entirely by naval agency, which was the prototype of all British machines. The chief point of its design, and on which it differed from other caterpillar machines, was its rhomboidal shape and all-round track, which were the invention of Lt. (later Lt.-Col.) W. G. Wilson, of the Admiralty landships committee, working in conjunction with Mr. (later Sir) W. Tritton. This machine, afterwards known as the Mark I. Tank, successfully underwent its official trials on Feb. 2.²

As has been said, at the beginning of the war the solution of the problem of enabling a frontal attack on trenches to be carried out had been thought to lie very largely in bombardment by artillery. But the futility of the limited bombardment by field guns with shrapnel shell, which was all that was possible for some months even against such comparatively weak defences as the Germans at first held, became apparent. Then, in reply to

¹ For purposes of secrecy the name "Tank" had been applied in Dec. 1915 to the experimental machine under construction, then known as a "landship," in a report by a sub-committee of the committee of Imperial Defence. It was suggested by two officers connected with that committee. The experimental machine was afterwards known as Big Willie, and, though a male, as "Mother."

² For the origin of the tank see the Minutes of the Proceedings before the Royal Commission on Awards to Inventors, Oct. 1919.

the insistent demand from the front the national energies had been turned to the making of guns and ammunition of all types, and prodigious quantities had been produced. But after the battle of Loos it began to be realized that even a great concentration of artillery and the expenditure of an immense amount of ammunition in a prolonged bombardment from guns of all calibres was not necessarily effective against such defences as the Germans had created, and could not insure that the assaulting infantry would not be held up by uncut wire and suffer terrible loss from concealed and protected machine-guns. Some other means of dealing with the numbers of these weapons which would survive a bombardment even of the heaviest nature was necessary. As a result of the performance of the experimental tank in Feb. 1915, G.H.Q. France came to the

FIG. 1.—Mark I Tank.

conclusion that such machines might be of some assistance, and made a demand for 40¹. This number was increased by the British War Office to 100, and supply was undertaken by the Tank Supply Committee of the Ministry of Munitions, composed of members representing interests directly concerned, under the chairmanship of Maj (later Sir) Albert Stern. Orders were placed on Feb. 12, and production was commenced at once with the utmost secrecy, under great difficulties of labour and material owing to the great national effort then in full swing to produce munitions of all sorts.

During this initial period of manufacture various minor improvements of the original design were incorporated. The

¹ The first order placed by the French army headquarters, without awaiting the construction of an experimental machine was for 400 machines, and this was increased to 800.

sample machine, in accordance with the original specification for a machine-gun destroyer, was armed with two 6-pdr. guns and three Hotchkiss machine-guns. It was soon realized that, though effective for its purpose, this armament was deficient in man-killing fire-power for self-defence in the event of attack by large numbers of men, and it was decided to arm a certain proportion of tanks with four Vickers machine-guns instead of two 6-pounders. They were known as "females," the gunned machines being known as "males." The total number under construction was 150, half males and half females.

The Mark I. Tank (see figs. 1 and 2) —Details of this machine are given in the table on p. 697, but since all the succeeding machines were a development of it, some further description is given. Its main characteristic was the all-round track, which gave it its climbing power. This was perpetuated in all the British heavy tanks, though in the medium, or "Whippet," tanks evolved later, the same result was obtained by the projection of the tracks which were not under the machine. The essential value of both forms of construction was that whatever the fore and aft angle of the machine with the horizontal a gripping surface was presented. This was achieved by the high, curved bows, rendered possible by combining the body and the chassis of the machine and using the sides of the body to support the tracks. The length was 32 ft. 6 in., over all, and 21 ft. 5 in. without the tail. The width was 13 ft. 9 in.; the height 8 ft. 2 in. Power was given by a six-cylinder sleeve valve Daimler engine of 105 H.P.; transmission consisted of a cone clutch, primary (two speed) gear box (controlled by the driver) differential secondary (two speed) gears, actuated by hand levers, one to each track, and chain drives to the driving sprockets at the rear of each track. There were thus four speeds ahead. This system necessitated a "gearsman" at each side, and was inconvenient and clumsy. The petrol feed was by gravity. There was no silencer. The armour plate varied from 12 mm. thickness in front to 6 mm. at the top and on the belly, the only part proof against the German "K" (armour-piercing) bullet being that 12 mm. thick. The armament of the male tank comprised two 6 pdr. guns, one on each side and four Hotchkiss machine-guns, and that of the female tank two Vickers machine-guns on each side and three Hotchkiss machine-guns. Owing to the pressure of time certain details in the design and equipment of the machine were adopted in order to employ material which was in production and quickly obtainable without waiting for special manufacture. The power unit, including the engine, with gear-box and differential was adopted because it was the standard power unit of an existing tractor and already in production. The 6-pdr. gun was adopted not because it was considered the best for dealing with machine-guns (the 2 pdr. automatic gun was originally specified), but because the Admiralty had a large number of these guns in hand and promised to supply the requisite number to the army. The 6-pdr. proved, however, to be a very good weapon for its purpose. The male tank carried 324 rounds of 6-pdr. common shell for the 6-pdr. gun and 6,272 rounds of S.A.A.; the female carried 31,232 rounds of S.A.A.² The crew consisted of one officer and seven other ranks. The driver sat with the officer in the conning tower in front. The total weight of the male tank when loaded was 28 tons; of the female 27 tons. The average speed across country was 2 in. per hour, and the radius of action, nominally 23 m., averaged 12 m. over rough ground. The

² It was originally proposed to carry a certain proportion of case shot. This was not done, but it was found necessary later to do this.

productive of valuable lessons, but they were obtained at the cost of discounting the future. It was in the face of a considerable amount of scepticism that the machines took their place in the battle-line, and those who did not believe in them, without looking beyond the lack of any startling success achieved on a great scale, were not slow in their condemnation. But one thing the tank had definitely proved: *The machine-gun and the barbed wire entanglement no longer ruled the infantry battle.* In the tank, still experimental and imperfect as it was, they had found their master. At last attacking infantry could meet the defence on more than equal terms.

On the part of the tanks themselves there was mechanical failure of machines, which were the first of their kind, tried under more difficult conditions than those which they had been designed to meet. The specification in which they had been constructed had been based on the requirements of the spring of 1915 at a time when the prolonged shelling, such as in 1916 and later rendered whole tracts almost impassable even by infantry, was undreamt of. At the Somme the tanks had to cross a dry "crumpled" area, and at the Ancre a combination of "crumpled" area and morass. There were, in addition, breakdowns due to faulty design and to the unexpected wear and tear of certain parts of the machinery, which only experience could have shown should have been of special material and which were, moreover, practically worn out by practice and demonstrations before the action. Failures were also due to the lack of time for the complete training and practice of the crews; to insufficient preparation in the way of reconnaissance and supply services, which for such complicated machines necessitated very complete organization. On the other hand, many of the commanders at whose disposal tanks were placed had no idea of their capabilities, weaknesses or limitations. Nevertheless, the outstanding brilliant exploits of single machines which did not break down, the great saving of life for which the tanks as a whole were responsible, and the demoralizing effect of their appearance on the enemy and the great encouragement afforded to the British infantry, clearly showed that the machines were sound in principle, only needing improvement in detail, and that those handling them required more experience in this new form of warfare.

As a result of its trial it was decided that the new Arm should not only continue, but should be expanded to a force of 1,000 tanks. After the fighting on the Ancre the unit did not again go into action till April of the following year, which allowed of a period for expansion, reorganization and training, and the incorporation of improvements to machines.¹ The expansion of the Heavy Branch of the Machine-Gun Corps was to be on the following lines: there was to be a fighting headquarters in France and an administrative headquarters in England.² The six original companies were to be expanded to four battalions in France and the two companies at home to five battalions, or nine battalions in all. The unit therefore reverted to its original battalion organization. It was eventually to comprise three brigades, each of three battalions, each battalion of three companies and a workshop, each company consisting of four fighting sections of five tanks each and a headquarters section of four tanks, or 72 tanks to a battalion. The number of tanks per section was shortly afterwards reduced to four, making 20 per company or 60 per battalion. These brigades were formed at the beginning of 1917, and the organization continued unchanged until June, but though the personnel was being raised and trained as far as possible on this extended scale, the supply of tanks did not keep pace, so much so that on April 1, when it was decided that the tanks should take part in the battle of Arras, only 60 Mark I. and Mark II. machines could be counted on for action.

In Feb. 1916, when the original Mark I. tank was still in its experimental stage, designs had been got out for a Mark II. machine and a Mark III. machine, both of which were slightly improved Mark I tanks. After the Somme battle certain modifications which were found necessary were incorporated, and in

!The most important improvement was the improvised "unditching beam" which was introduced to assist a tank to extricate itself when stuck. In the later types a specially designed contrivance was part of the equipment of the machine

1st.-Col. (afterwards Maj.-Gen.) H. J. Elles, R.E., was appointed colonel commanding the unit in France, Brig.-Gen. F. Gore Anley being appointed administrative commander of the tank training centre in England on Nov. 9. In May 1917 Brig.-Gen. Anley was succeeded by Maj.-Gen. Sir J. E. Capper. The training centre was moved to Bovington in Dorset.

Oct., in order to keep up continuity of supply, orders were given for 50 machines of each type (making 350 tanks ordered in all) pending the decision on the design for the 1,000 asked for by the army, in Sept. The chief improvements consisted of the abandonment of the tail, as already mentioned; the addition of "spuds," or fins, to the track plates, to give a better grip; and the provision of improved rollers. The Mark III. machines were also intended to have thicker armour to resist the "K" bullet. In regard to the 1,000 new tanks preliminary orders to collect material were given to the manufacturers in Sept. At the end of the month when it was learnt that these machines could not be ready by March 1 (partly owing to the manufacture of spare parts necessary for the existing tanks), the demand was cancelled, but was renewed two weeks later. This is men-

FIG. 3.—Mark IV. Tank.

tioned to show that military opinion as to the advisability of proceeding with the new weapon was not unanimously favourable. The 1,000 machines were to be of the type known as the Mark IV, which was a much improved Mark I. tank. It was then anticipated that this number could be delivered by the end of June. Owing to various difficulties this estimate was not fulfilled, but sufficient machines reached France in time to equip two battalions for the attack on Messines in May; and it was the standard British tank during 1917 and 1918.

FIG. 4.—Mark IV, Tank.

The Mark IV tank (see figs 3 and 4) —The first advance from the original weapon was the same in size and general design, with certain improvements. There was no tail. The track rollers were better. The sponsons could be housed within the tank for rail transport. The Lewis machine-gun was installed instead of the Hotchkiss machine-gun (this was not an improvement and was reversed later). A better radiator was fitted and also a silencer. The width of the driver's cab was increased to allow of wider track shoes. The petrol tanks were placed outside the tank at the stern. A short 6-pdr. gun was adopted. Detachable spuds were fitted to the tracks, and unditching gear provided. The entrances and exits were more accessible.

During the Verdun offensive early in 1916 it had occurred to those responsible for the production of the fighting tank that one reason why the Germans had been unable to keep up the initial pressure of their attack was their inability to bring up their artillery and ammunition over the shelled and entrenched area so as to keep pace with their advance; and that if they had been in possession of guns mounted on self-propelled carriages, or carriers on caterpillar tracks, it would have assisted them greatly. A design was therefore prepared in July of a "gun-carrying" tank (see fig. 5), to carry a 60-pdr gun or 6-in. howitzer which could be fired from the tank if necessary or conveyed by the tank and fired from the ground. Of these machines

FIG. 5.—Gun-carrying Tank.

48 were made, delivery in France commencing in July 1917. They appear to have been employed as much for the conveyance of ammunition and stores as for the purpose for which they were designed. In Dec 1916, also, the design of the "Whippet," the Medium Mark A. tank, (see figs. 6 and 7) was commenced. Of this type 200 machines were produced, delivery in France starting at the end of 1917. It was evolved to be complementary to the heavy tanks and to meet the demand for a speedier, handier machine which could be produced in large numbers. Its main points were its increased speed, nominally 8 m. per

hour on the flat, and an average across-country of 5 m. per hour, and its lightness, one-half that of the Mark I. machine. It was also easier to transport by rail. Each track was driven independently by a four-cylinder 45 H.P. Tylor engine. Transmission was by cone clutches to gear boxes of the constant mesh type, giving four speeds forward and one reverse. The design was largely due to Sir W. Tritton. Thus, at the end of 1916, in addition to the first type of heavy tank in the field, measures were in hand to supply a much improved pattern of that machine (Mark IV) and also a lighter type—the "Whippet."

FIG. 6.—Medium Mark A. or "Whippet" Tank.

In the field, though there was still considerable doubt as to the value of tanks, the next six months, from Oct. 1916, were, as had been said, a period of expansion, organization and training, and preparation for the operations of 1917. The training was always handicapped by the paucity of machines; and it was found necessary not only to educate the members of the new arm itself but also other arms and the staff. Headquarters, schools and rest camps and the usual organization of a large unit were established. The next action in which the tanks took part was the battle of Arras on April 9, when an attack was carried out by the I., III. and V. Armies in order to penetrate the German line by a sudden blow and allow of an army corps and two divisions of cavalry to break through. From the point of view of tanks it does not require much comment. Only 60 machines were available, and they were again not employed in

Fig. 7.—Medium Mark A or "Whippet" Tank.

a mass for a quick penetration but for "mopping up" operations along the whole front.¹ More complete preparations were made for their cooperation than at the Somme. The battle was prepared by a prolonged bombardment, and was also preceded by heavy rain at the last moment, which combined to produce a sea of mud pitted with craters. The Vimy Ridge was captured by a rush of the Canadians which rendered tanks unnecessary, and on other parts of the front they had varying success, but gave valuable assistance. Against Bullecourt on the 11th, where they attacked without artillery preparation in the snow, the attack was a failure, though two tanks penetrated five miles behind the German front line, when they were captured. Fighting continued till the 22nd. The cavalry were prevented from breaking through by the usual obstacles—barbed wire and machine-guns. It was on the first day of the fight that the first German "tank trap" was discovered consisting of a deep covered-in pit. Again the main lesson learned was that tanks should be used in mass and not dispersed. After this battle an expansion of the Heavy Branch, Machine-Gun Corps, from 9 to 18 battalions (nine of heavy tanks and nine of medium machines) was decided on. But at the end of June this expansion was suspended owing to shortage of man-power, as it was apparently not yet realized to what extent the tanks reduced casualties. Before the next action, the battle of Messines, a certain number of the new Mark IV tanks had been received and several of the old Mark I and Mark II. machines had been converted into supply tanks for carrying tank stores to the fighting machines, a very great advantage the want of which had previously been much felt. In the attack on the Messines-Wytschaete Ridge, which started on June 7, 76 Mark IV. and 12 supply tanks took part. The operations in this case approximated to the "assault" in the old form of siege warfare and depended mostly on an intense bombardment, lasting from May 28 to June 7, and the explosion of 20 large mines. During

¹ "Mopping up" consisted of disposing of small bodies of the enemy, especially such as had escaped the bombardment and allowed the first line of the assault to pass them.

the infantry advance on Wytschaete the creeping barrage proved so effective that tanks were only necessary at different spots to overcome individual machine-guns. They advanced in two lines, the first of 40 machines, going forward at zero (dawn), and the second, of 34 machines, at 3 P.M. to the Oosttaverne line, where their help was very valuable. Apart from the debated point whether the third battle of Ypres should ever have been fought or not, the work of the tanks in it needs still less comment than at Arras or Messines. In spite of remarkable feats accomplished by them, especially the capture of the Cockcroft, a nest of strong points, on Aug. 19 with a loss of 15 infantry, it was, on the whole so far as they were concerned, a failure, and a failure which was inevitable and to be expected under the conditions which existed. They had to act in a low-lying area which had been converted into a potential swamp through the destruction of the drainage system by the artillery of both sides, rendered still worse by the churning up of the surface into a wilderness of craters, which were filled by heavy rain just before the battle. The only means of approach across this morass were the causeways, which were naturally kept continuously under fire by the enemy. Preceded by many days of intense bombardment the attack commenced on July 31, and as it continued the rain made matters worse. That tanks should have been expected to function under such conditions, when, independently of the enemy's action, even the infantry were unable to move forward, is astonishing. It shows that those responsible for the decision to employ them were ignorant either of the situation or the limitations of the machines, or both.

It was not till Nov. 20, when the tanks had been in France over a year, that they were given an opportunity of showing of what they were capable when employed on a large scale, in a manner calculated to exploit their peculiar attributes, and under favourable conditions. As this was a turning-point in the history of the new weapon it is of importance that it be described in detail.

During 1916 and the greater part of 1917 the tanks had been thrown into the fight in dispersed detachments to assist in overcoming certain points of resistance, and somewhat casually as an aid to the attacking infantry. The conditions, also, had usually been such as to render success doubtful, sometimes impossible, and in any case of a minor nature. In several instances they had succeeded in achieving their immediate object and had undoubtedly saved many lives. In others they had failed. As a consequence it was seriously discussed whether tanks should not be abandoned as useless.

But those responsible for the Tank Corps (the name of the unit had been changed to "Tank Corps" at the end of June) had been concerned in thinking out an operation which would not only be strategically valuable, but would enable the corps definitely to prove its worth and establish a confidence in itself, which, never very marked on the part of General Headquarters, had recently been much shaken. Broadly, the scheme consisted in launching without any preliminary bombardment a surprise attack on a large scale with as many tanks as possible over ground suitable for their action, i.e. reasonably hard soil which had not been shelled to pieces. The area chosen was that near Cambrai, in the re-entrant of the Canal d'Escaut between Ribecourt, Crèvecœur, and Banteux, which consisted of almost unshelled rolling downs of chalk. The attack was originally intended to be of the nature of a "raid" (this was not adhered to in its execution) carried out by an advance at dawn of three lines of tanks, the first of which would make straight for the enemy's guns, previously bombed from the air, to be followed up by the second and third; artillery coöperation to be confined to counter-battery work and the destruction of communications and depots, etc., behind the German front line. The essential points of the plan were surprise and speed. The project was put forward and approved, and the result was the battle of Cambrai, which took place on Nov. 20.²

² The action as fought was in almost every detail the execution of the plan put forward officially for the employment of the tanks by Col. Swinton in Feb. 1916, 22 months previously.

Further details of the plan were that the artillery barrage of shrapnel and 11 E. shell should open on the enemy's outpost at zero hour (6.20 A.M.) and be advanced by stages of 250 yd. just ahead of the tanks and concentrated on special points. The tanks were to go forward at zero hour in sections of three machines, sections being allotted to different objectives according to the strength of the latter. Each section was composed of one vanguard tank and two main body tanks. The former was to lead and protect the advance of the two other machines, behind which followed the infantry in parties of varying size, marching in sections in single file. As the Hindenburg trenches, some 12 ft. wide, would have to be crossed each tank was to carry a specially made fascine 10 ft. long and 4½ ft. in diameter to drop into the trenches to assist in the crossing. Special machines were fitted with drag grapnels in order to drag aside the wire entanglements which were known to be exceptionally thick and strong, for the passage of the cavalry. Great precautions were taken to maintain secrecy, upon which so much depended, and extremely careful preparations were made in the way of reconnaissance, the training of the infantry to act with the tanks, the movement of machines, and the formation of dumps of the necessary stores. For instance the preliminary movement of the tanks necessitated 36 special trains, and the material collected in dumps included 165,000 gal. of petrol, 55,000 lb. of grease, 5,000,000 rounds of S.A.A. and 54,000 of 6-pdr ammunition. Three brigades (nine battalions) of tanks took part in the attack, with two army corps of three divisions of the III Army, a cavalry corps and 1,000 guns. In all there were 378 (Mark IV.) fighting tanks and 98 administrative machines.

Log on the morning of Nov. 20 assisted the attack, which was carried out as arranged, the tanks following the barrage and the infantry the tanks. The operation was an amazing success and came as an absolute surprise to the enemy, most of whose infantry were panic stricken and bolted or surrendered, the garrisons of certain strong points alone offering a determined resistance. Assisted by the tanks, the infantry by evening had occupied Marcoing,¹ Bois des Neufs, Premy Chapel, Havrincourt, Graincourt, Aneux, Noyelles. Next day, and on the 23rd, 25th and 27th, further progress was made, but the tank units which had been fighting continuously were disorganized and the crews physically exhausted; and the mistake had been made of not keeping a small proportion of tanks in reserve. On the 27th the impetus of the attack died out with practically no more ground gained than had been won on the first day, where the tanks, starting from a base of 13,000 yd. length, had in 12 hr., and at a cost of some 4,000 casualties, enabled the enemy's zone to be penetrated to a depth of 12,000 yd. (at the third battle of Ypres an equal extent of penetration had taken three months), and 8,000 prisoners and 100 guns to be captured. And their action had obviated the necessity for a preliminary bombardment (which would have cut up the ground and rendered any rapid advance of infantry impossible, and brought a concentration of enemy's reserves), and also the usual wire cutting artillery fire, which together would have cost many millions of pounds. (An estimate places the cost of the preliminary bombardment at the third battle of Ypres at approximately £22,000,000. A similar bombardment at Cambrai would possibly have cost more, as the German wire was on the reverse slopes of the rising ground.)

In numbers the personnel of the tank corps employed in the fight amounted to a little over 4,000 of all ranks, or the strength of a strong infantry brigade. The fact that there were no larger bodies of infantry ready to reinforce the tired troops and press the advantage gained, and that the cavalry did not break through to Cambrai as was intended, was not owing to any failure on the part of the tanks, which achieved more than had been promised. The absence of any large force to take advantage of the opening made by them tends to show that it was not believed that they could do what they actually did accomplish, and that their complete and extraordinarily speedy success was as much of a surprise to British Headquarters as it was to the Germans. For nearly three years efforts had been made by both sides to force a way through the enemy's position quickly. At Cambrai a door was suddenly flung open and there was no force to press through. The success achieved by the surprise counter-attack by the Germans on the 30th also had nothing to do with the previous action of the tanks, but its effect was to discount the whole British victory including their performance. Against the southern portion of this German counter-attack a brigade of tanks which were hurriedly collected proved their worth in a defensive rôle, and gave invaluable assistance in stopping the onrush of the enemy.

The success of the tanks at Cambrai on Nov. 20, and all that it implied, gave as much food for thought as had the first use of gas by the Germans in 1915, unattended, however, by the horror of the means employed on the first occasion when a surprise penetration was effected by either side. It has been described as the "Valmy of a new epoch in War, the epoch of the mechanical engineer."² But it is doubtful if the truth of this

statement has been fully appreciated even three years after the war. Even so, the effect of this action on the Allies, and also on the Germans, was immediate and far-reaching. It almost established the fact, for which the protagonists of the tank had been endeavouring to gain acceptance for many months, that the new Arm, used properly, was a serious factor in warfare which could not be put aside and ignored. And yet, though opinion in regard to the tanks had changed, even at that period when the immense losses suffered in the attempted offensives of the previous eighteen months had rendered the problem of man-power so acute, the crucial point was still not realized that an actual saving in life and economy in man-power would be gained by the development and whole-hearted employment on a very large scale of the mechanical Arm. And steps were not at once taken for a great expansion. The increase of the Tank Corps previously deferred was agreed to; but a proposed further expansion, based directly on the experiences of Cambrai, was not approved. And later, in April 1918, even the agreed increased establishment was again temporarily suspended after the German offensive in order to meet the demands for infantry reinforcements, and was not completed until after the striking successes gained by the tanks in July and Aug. 1918.

After Cambrai all ideas of attempting to prosecute the offensive were abandoned, and there ensued a period of preparation for resistance against the attack which was expected as the result of the reinforcement of the German strength on the west, rendered possible by the defection of Russia. To assist in meeting this, the Tank Corps, now of five brigades, or thirteen battalions, with 320 Mark IV. and 50 Medium A machines fit for action, was in Feb. 1918 distributed in detachments over some 60 m. of front.

During the second battle of the Somme, from March 21 to the end of the month, the part played by it was to coöperate in various local counter-attacks, its action being generally useful in assisting to delay the enemy's advance, as the German infantry would not as a rule face tanks until their guns were brought up. But out of the total, some 170 machines alone went into action usually and inevitably in hasty, improvised operations carried out during the general retrograde movement. Many machines were lost and their crews employed on foot as Lewis Gun sections. It was during this period that the new "Whippet" machines made their début with great effect. Generally speaking, the tanks were too scattered for full value to be obtained from their action. The corps also took its share in repelling the second German thrust against the British, which started in the Lys area on April 9, during which three battalions fought, some of the personnel of the lost tanks fighting on foot as a Lewis Gun brigade. It was in this quarter, near Villers Bretonneux, that the first duel between tanks—possibly a presage of future warfare—took place.

The lack of decisive results obtained by the small detachments of tanks acting in improvised counter-attacks in the general defensive seems to have revived the lingering prejudices of those who were hostile to the arm, and who maintained that the mass action of Cambrai could never be repeated. However, in spite of this, progress was made in May and June in preparing for the future offensive, the chief point of note being that the new Mark V. (heavy) tanks, which were a great improvement on previous models, being much handier and also more mobile, were arriving at the rate of 60 machines per week. On July 4 occurred the action which probably finally dispelled the doubts of the most conservative and reactionary. This was the surprise attack of Hamel, a deliberate offensive and not a defensive counter-attack, in which recently received Mark V. machines coöperated with the Australians. This fight was an example of a perfectly organized action and of the advantage of previous careful training to act together of tanks and infantry, and was a speedy and complete success, achieved at the low cost of some 700 casualties. One feature was the special power possessed by the new and speedier tank of destroying machine-guns, many of which were rolled over and crushed.

The logic of facts was irresistible, and after this action the coöperation of the tanks was thenceforward accepted, not only as a useful adjunct but as an absolute necessity, for all offensive operations. On July 17, at the battle of Moreuil, one battalion of tanks coöperated with three French divisions in a most suc-

¹ The information of the capture of this village was sent back by a wireless signal tank, and was received at Albert 10 min. after the troops entered Marcoing.

² *Tanks in the Great War*, Col. J. F. C. Fuller, p. 153.

successful attack on a similar plan launched after one hour's preliminary bombardment.

July 18, the date of the great French victory of Soissons, marked the turning point of the war. It depended on tanks, and was rendered possible by their proper employment in mass and as a surprise. In fact, as the recent British offensive on a smaller scale had been, it was based on the battle of Cambrai. It was followed by a similar operation, the battle of Amiens on Aug. 8 which opened the British strategic offensive.

This battle was also based on the power of the tank arm, and was designed and organized to derive the utmost value from it and to give it every chance to perform its proper, logical function in a general operation. The tactics to be employed by the tanks were an elaboration of those employed at Cambrai modified by recent experience and adapted to the improved machines available. The attack was carried out by three army corps, with three divisions in reserve, a cavalry corps and 11 tank battalions. In regard to the tank battalions they were now better equipped than they had been. Nine were equipped with the new Mark V machines (36 each), and two with the "Whippets" (48 each), or in all 420 fighting machines. There were also 42 tanks in reserve, 36 supply tanks, and 22 gun-carriers, or 580 machines in all. The "Whippet" tanks were to act with the cavalry. There was no artillery bombardment, and the tanks advanced with the barrage at "zero" hour. The heavy guns were used for counter-battery work and the field artillery moved forward in close support of the infantry. Noise barrages (made by low lying aeroplanes) were used to drown the sound of the tanks' approach. On the first day the maximum advance of the tanks was 7½ m., and they continued in action for four days till the 11th.

The battle of Amiens was a tremendous blow, both material and moral, to the Germans, who, besides casualties, lost 22,000 prisoners and 400 guns, and the victory was admittedly very largely due to the tanks. Amongst other lessons learned it was again found that these machines, like other arms, required a reserve to keep up the pressure after the first day of action, and that the limit of endurance of the heavy machines before overhaul was three days, that they were suited for trench warfare, the medium machines for open warfare, that the heavy supply tanks should be replaced by a light cross-country tractor, that wireless and aeroplane communication, as then developed, was not so certain as that by galloper; that it was a mistake to tie up tanks to cavalry, for, during the approach they could not keep up, and during the fight were kept back by the cavalry, which under hostile machine gun-fire had to retire or move to a flank until the tanks disposed of the machine-guns, and that machines of greater speed and greater radius of action were necessary. According to one authority,¹ if machines capable of moving at 10 m. an hour with an endurance of some 100 m. had been available, the German forces south of the Amiens-Roye-Noyon road might have been cut off and the end of the war greatly accelerated.

July 18 and Aug. 8 were not only victories for the French and British over the Germans, they were victories over their opponents for the tank arm in each army. In regard to the British it is sufficient to say that up to Nov. 5, their last fight, no attack took place without tanks. They cooperated in every offensive including such important operations as the battle of Bapaume, and the second battle of Arras, the battles of Epehy, Cambrai-St. Quentin (when the Hindenburg line was broken), the Selle and Maubeuge. Latterly, indeed, during the "war of movement" which set in after the Hindenburg line had been passed, advancing infantry when faced by the German rear-guard machine-gun posts almost invariably halted for tanks to come up and dispose of them before they moved forward.

So far as statistics can show what a part they played, the following facts speak for themselves. By the time of the battle of Amiens much of the personnel of the Tank Corps had been in action 15 or 16 times, and during the 95 days from that time to the Armistice tanks (to the number of 1,993) were engaged in fighting on 39 days. The casualties, killed, wounded and missing were 598 officers and 2,826 other ranks. These, though heavy in relation to the strength of the unit, which was under that of an infantry division, were not heavy for 39 days hard fighting if it be borne in mind that in pre-tank days it was not unusual for an attacking division to suffer 4,000 casualties in one day often without reaching the objective.

The final despatch of the Commander-in-Chief of the British

armies contained the following words:— Since the opening of our offensive on August 8th, tanks have been employed on every battlefield, and the importance of the part played by them in breaking up the resistance of the German infantry can scarcely be exaggerated. The whole scheme of the attack of August 8 was dependent upon tanks, and ever since that date on numberless occasions the success of our infantry has been powerfully assisted by their timely arrival.

It would not be too much to say, that in spite of any artillery assistance, the series of overwhelming, immediate and economical (both in life and treasure) victories won at Amiens and afterwards would have been absolutely impossible without tanks, as would the whole scheme of the strategic offensive which depended for its execution and cohesion on the prompt and certain success of these attacks. And this statement, which is tantamount to an expression of opinion that human bodies cannot vie with armoured machines against wire and machine-guns, is no disparagement of the British infantry. It is one which would be borne out by the survivors of Neuve Chapelle, Loos and the Somme.

After the action of the Somme a few tanks were at the end of 1916 despatched to coöperate against the Turks in Palestine, where the situation was somewhat similar to that which had arisen on the western front. It was doubtful, at first, whether the machines, some parts of which were out very quickly, would operate in the sandy desert; but it was found that the dry sand was less harmful than the mud of Flanders, and the tanks in fact stood the test well, and covered a surprising number of miles, though they happened to be machines already partly worn out in training. Only eight tanks were sent out, which was far too small a number to enable any very important result to be obtained in a field where the bold use of tanks in force might have had a decisive effect. The terrain favoured their action, and the strength of the defence, doubtless owing to German influence, lay largely in machine-guns. Their entry into action was not a surprise, for the enemy were aware of their arrival in the country, and they were used on two occasions only, at the second and third battles of Gaza, on April 17 and Nov. 1 1917, all the machines taking part.

Though the tasks set before them at both battles would have been more suitable to a force of machines five times their number, they rendered in each case great assistance and saved much loss of life. As a result of their help, which was greatly appreciated by the infantry, who were, of course, chiefly affected, an effort was made early in 1918 to obtain a number of "Whippet" machines for action against the Turkish rear-guard during the further advance. But this demand synchronized with the German offensive on March 21, and no machines could be spared for a theatre peculiarly suited to them.

So far an outline has been given of the main tank operations, and the development and expansion of the unit. The former showed a gradual increase of the scale on which recourse was had to the machines, and an elaboration in the preparations made and the tactics applied. From the 40 fighting tanks which were allotted to the attack at Cambrai, the number rose to 580 of all types at Amiens nearly two years later, the latter being the greatest British tank action fought. And, according to the preparations which were being made at the time of the Armistice, any great offensive in 1919 would have been conducted with thousands of British tanks alone, leaving out of consideration the equally large numbers of French and German machines that would have been engaged.

By Aug. and Sept. 1918 the type of heavy fighting machine had been improved in design, reliability and speed, and a faster medium tank had been introduced. Measures had also been taken to equip, for cross country work, all the battle services for the tanks. There were fighting tanks; supply tanks, to carry up ammunition, drinking water and stores; gun-carrier tanks, used for the same purpose, as well as for conveying artillery and trench mortars, both sometimes dragging sledges similarly loaded; wireless signal tanks; salvage tanks; all working on a coördinated system toward the maintenance or pressure on the enemy with the maximum of efficiency. And to assist in doing this there was a complete repair organization, the central workshops, with its advanced stores and salvage companies. For a major operation, the system of attacking with a small number of machines divided up into separate detachments had been abandoned and the proper tactics of mass attack in as large force as possible in definite formations to meet different conditions, with reserves to keep up the advance, had been adopted. Signal

¹ *Tanks in the Great War*, Col. J. F. C. Fuller.

units had been formed. The elementary system of signalling with flags and with daylight lamps to aeroplanes had been elaborated, pigeons were used, and wireless signalling had been reintroduced, and wireless telephony with aeroplanes had been tried, but not with much success. Intimate coöperation with low-flying aeroplanes had been organized, especially in the direction of noise barrages, machine-gunning and bombing the enemy, chiefly of the hostile guns, and dropping information, as also observation for counter-battery work, and smoke-screens were employed. In short the battle was organized to include and harmonize with the new instrument.

In regard to the future of the tanks, had the war not ended in 1918, certain proposals for expansion for the 1919 campaign, made at the Inter-Allied Tank Committee in Jan. 1918, were again brought up in July, and new establishments for the increase of the Tank Corps to a strength of 34 battalions were sanctioned in Oct. This strength, together with the number of some 6,000 machines which it was hoped to produce for 1919, is in itself evidence of the importance attached to the tank arm at the close of the war. Its strength in the field in Oct. 1918 amounted to 12,355 of all ranks, whilst many thousands more were under training at home.

The work of designing and producing the different types of machines which took the field, or were almost ready to do so, necessitated a very large organization. In addition to the Medium Mark A. (Whippet) machines, of which, as has been stated, delivery began in France at the end of 1917, the following types were evolved.

designed so as to be made up of parts manufactured in England and the United States, and was to be engine either with the American 300-H.P. Liberty, or the British 300-H.P. Rolls-Royce, engine. The engine-room was separated from the fighting-chamber by a bulkhead and the ventilation was improved.

The Mark IX. tank (Infantry tank). The design for this was begun in Sept. 1917. Thirty-five machines were made, but none was actually used. It was a long machine with space in the centre to carry 50 infantry or 10 tons of stores.

The Medium B (Whippet) tank. The design of this, which differed from that of the Medium A, was commenced in June 1917. The shape was more like that of the heavy tanks. It had a four-cylinder 150-H.P. Ricardo engine. Forty-five machines were made, but none used. In all, 2,636 British tanks were constructed.

The production of the tanks on the first order for 150 which, were in action in 1916, six months after the order had been placed, was, as has been said, a remarkable achievement. After that time supply was carried out by the Mechanical Warfare Supply Department of the Ministry of Munitions, working in conjunction with the War Office and G.H.Q. in France. The subject was handled by a succession of committees, composed of those concerned, which endeavoured to obtain coöperation and the allocation of responsibility as between the army, which demanded machines and changes of design, etc., and those who had to meet these demands. In Aug. 1918, control was taken over by a Tank Board, to coördinate all sides of the question of supply. There were naturally considerable difficulties in administration of the production side of this weapon improvised during hostilities, at a time when the manufacturing resources of the country were already deeply committed in satisfying the

Fig. 8.—Mark V. Tank.

The Mark V. tank (see fig. 8 and table A). This was in design and size the same as Mark IV, but it was superior to it in the following particulars:—The engine, a 6-cylinder Ricardo engine of 150 H.P., was more powerful and was expressly designed for the tank. The manoeuvring powers were improved by one-man control and an epicyclic gear. The means of observation were improved. The unditching gear could be worked from inside the machine. Better means of clearing the tracks of mud were provided. The design for this was begun in Oct. 1917 after the experiences of Messines and the third battle of Ypres, and was to meet the requirements as then known. Some of these machines reached France in time for the attack on Hamel on July 4 1918, and this tank was the principal machine of all the subsequent fighting. In all, 403 were made.

The Mark V. Star tank was the same as a Mark V. machine, with 6 ft. added to the middle of its length. It could cross wider trenches (14 ft.) than the Mark V. machine, and could carry about 20 men in addition to the crew. The design was not started till Feb. 1918, 32 machines being made, of which some were delivered in time for the battle of Amiens. The tank was too long to be very handy.

The Mark V. Two-Star tank was the same as the Mark V. Star, but with a 225-H.P. Ricardo engine. Design was started in May 1918, one being made but not delivered before the Armistice.

The Mark VI. tank was intended to be the same size as the Mark IV, with an improved transmission (the Williams-Janny variable speed gear), but did not get beyond the design stage.

The Mark VII. tank. This was 3 ft. 6 in. longer than the Mark IV and Mark V. It had a 150-H.P. Ricardo engine and a variable speed gear. Seven were made, but none was used in the field.

The Mark VIII. tank. The design for this machine was commenced in Dec. 1917; seven machines were made, but none was employed in the field. It was larger (34 ft. 2½ in.) than any other tank, and was

urgent demand for munitions of other kinds. The lack of continuity in the demands, also, which fluctuated as the value of the tank varied in the opinion of the army in the field according to its success in action, made continuity of work and accurate forecasts of output almost impossible. There were also questions of obtaining the necessary labour, manufacturing facilities, raw materials, and that of priority amongst so many competing requirements for carrying on the war. The problem was complicated by the multiplicity of special component parts and fittings required, the great wastage of machines from action in the field, and the quite unexpected wastage by wear and tear of certain parts, some of which, as the design of the machines developed, became obsolete before they could be used, and there were the technical difficulties of ensuring efficiency in details, of which the only test could be use in the field.

A great expansion in the sources of supply became necessary as the programmes of construction increased in size, and many engineering firms were engaged in the manufacture of the tanks in addition to the comparatively small number concerned in 1916 and 1917. Before the Armistice the supply of tanks was considered so important that men were relieved from the army to carry on production. The programme for 1919, including Inter-Allied production, which covered over 6,000 machines, required 193,000 tons of steel, 10,000 6-pdr. guns and 30,000 machine-guns, and an expenditure of £80,000,000. By the end

of the war, tanks were accepted as being the best and most economical means of arriving at a decision in the field, as the ratio of results obtained to material and man-power absorbed was greater than from any other means. In England development in design has since continued in the direction of the evolution of tanks possessing greater speed and a greater radius of action than that of the more or less embryonic machines which were evolved during the war, and also in the production of machines which can function either on land or on water. Success in these directions will endow the machine, originally improvised with the limited object of assisting the infantry to break through an entrenched line, with far greater powers.

FRENCH TANKS

It is not remarkable that allies fighting a common enemy, side by side in the same theatre of war and subjected to similar conditions, should have evolved a similar means of meeting them. And it would have been natural had they done this simultaneously, in a common effort, or at least with mutual knowledge from the beginning on the part of each of what the other was doing. Curiously enough, this was not the case with the British and French, the two nations concerned in the creation of the tank. Forced into being by the same causes, a remedy for the same disease, even suggested in form by the same mechanical prototype, the British tank and the French *Char d'Assaut* were conceived separately, and for many months developed on independent lines, the British ignorant of French intentions and the French ignorant of what the British were doing. In the case of the latter, as of the former, it was the difficulty experienced in carrying out the pre-war theories of infantry attack against a prepared defensive which finally led to the new machine, though the effect of the H.E. shell of the French field gun may have prevented its necessity being felt so soon.

The French owed their tank¹ to the foresight and pertinacity of Col. (later Gen.) J. B. E. Estienne of the artillery, who, during the retreat of 1914, perceived the desirability for having some means of transporting infantry under cover across obstacles and swamps and ploughed land. Later, during the summer of 1915, on seeing the caterpillar gun tractors in use in the field by the British, his ideas took a more concrete shape in the direction of a *cuirassé terrestre* (land battleship). This was to be a caterpillar-propelled machine 4 metres long, 2.60 metres broad, 1.60 metres high, weighing nearly 12 tons. It was to be provided with a petrol engine, to travel at a speed of 6 m. per hour on the flat, to be protected by armour up to 20 mm. in thickness, to carry an armament of two machine-guns and one light Q.F. gun for the attack of machine-guns behind shields, and to be capable of crossing trenches two metres wide and forcing its way through barbed wire. It was also to draw an armoured trailer carrying 20 men and equipment. This was worked out in greater detail, but was in essentials the same as the scheme put forward in England in Oct. 1914, except that as projected the *cuirassé* was to be somewhat of a hybrid between a tug to haul a transport filled with men and a fighting machine, and not purely a destroyer which would open out a way for men to advance on their feet. Actually, however, both types were developed as fighting machines. Both, also, were inspired by the Holt tractor, of the existence of which the British originator had knowledge before the war, and of which the French originator first became aware when he saw it at work behind the British lines. Before these machines were introduced by the British in the early part of 1915 for moving heavy artillery, tractors on the caterpillar system were practically unknown in France. Later some brought over from Tunis were employed with the army of the Vosges. After communicating with the commander-in-chief, Col. Estienne on Dec. 1 1915 put forward his ideas in an official letter with a request for an interview. This took place on Dec. 12, which date can be taken as marking the official conception of the French tank. After consultation between Gen. Joffre and Col. Estienne, and discussions between the latter and representa-

tives of the Renault and Schneider works during Jan., the French Army H.Q. submitted to the Ministry of War a demand for 400 tanks. These were to be of the design prepared jointly by M. Brillé of the Schneider Creusot Works, and Col. Estienne. For the French, therefore, this was the commencement of the solution of the problem of mobile protection for the infantry.

In regard to the French tanks, the year 1916 can be taken as one of gestation. The year 1917 covered the birth and infancy of the medium (Schneider and St. Chamond) tanks; the first half of 1918 the adolescence and maturity of the medium machines and the birth of the light (Renault) tank, and the last half of 1918 the adolescence and maturity of the light machine. But the period of gestation before the birth of the new arm, i.e. the appearance in the field of the *Artillerie d'Assaut*, or "A.S.," was, as in the case of the British Tank Corps, somewhat lengthy. Its promoters still had much opposition and many obstacles to overcome, for the question of production was handled by more than one department or directorate, a state of things which is usually bound to result in friction and delay. It appears, also, that whilst some officials were impressed with the vital urgency for expedition others were more concerned to conduct matters in accordance with the regular routine of peace procedure. But there was no intervention by an outside department or ministry to save the situation. It is not on record that the French Ministry of Marine collaborated in the creation of the *Chars d'Assaut*. On Feb. 25, after some inter-departmental discussion and trials of a baby Holt tractor, and without waiting for the construction of any experimental machine, an order was placed with the Schneider firm for 400 tanks, then called *tracteurs Estienne*, afterwards known as *Chars Schneider*, to be delivered within six months. This was only two weeks after orders had been placed by the British for the first 100 Mark I. tanks. So far the comparative progress in development of the new arm by the two nations had been as follows:—the idea of the tank had occurred at about the same time to both, the matter had been put forward officially by the British in the third month of the war and by the French 14 months later, the first actual order for machines, given by the British 18 months after war began, was followed by that of the French only a few days later. The British machines, however, took the field six months before those of their Allies. In addition to the 400 Schneider tanks a contract for 400 more machines of a different type was placed with the St. Chamond Works in April, without the knowledge of the commander-in-chief or of Col. Estienne.

Not long afterwards steps were taken for the formation and training of personnel for the new arm at Marly-le-Roi. In June French H.Q. received from British G.H.Q. official intimation of what was being done in England. Col. Estienne visited England, and after inspecting the Mark I. tank in the training area at Elveden reached three conclusions. One was that the two countries should collaborate in the production and coöperate in the use of the new weapon in the field. The second was that neither should forestall the other in employing it and so discount its maximum value for the Allies as a whole. On this Col. Estienne was specially insistent, because it was apparent that the British were far ahead in production and would probably be ready before the French. The third was that as a complement to the heavy, somewhat slow, French tanks, capable of negotiating almost any obstacle, the French should specialize in the production of a speedier and more handy machine, which would be to the British tank what field artillery is to heavy artillery, would perform the duty of a swarm of skirmishers in armour armed with a machine-gun, and would be capable of going wherever an infantry soldier could go. The scheme for light tanks did not meet with a favourable official reception, and sanction for the construction of 50 machines of this type was not given. Nevertheless designs were put in hand by the Renault firm and at the end of Nov. were so far completed that construction could have been started. Though no executive action was taken for some months, except that 150 machines for use as "command" tanks for the units of the *Artillerie d'Assaut* were given, this was the genesis of the Renault tank.

¹ For convenience the word "tank" will be used generally to describe the French machines.

The French classified tanks in three categories:—

Chars légers, machines weighing under 10 tons

Chars médiums, machines weighing 10 to 30 tons, which could be transported by rail on ordinary trucks.

Chars lourds, machines which would require specially constructed trucks for transport by rail.

As the medium tanks were the first constructed and used, their description will be given first. Both the Schneider and St. Chamond tanks were smaller and lighter than the British Mark I. or any subsequent pattern of heavy machine, and were, according to British nomenclature, males. The great difference between them and the British heavy tanks was that the designers of the former, in taking the caterpillar tractor as a model, had been content to employ tracks somewhat similarly placed under the body of the machine, and not extending all round it as in the case of the British heavies. The tracks were also shorter

FIG. 9.—French Char Schneider

than the full length of the body, instead of projecting well beyond it, at least at the front, as was the case with the British Whippets, and the French Renaults, and both tanks had a particularly "underhung" appearance. It was this arrangement of the tracks which militated against the climbing powers of the machines, whilst their comparative shortness limited the spanning powers across a trench.

The *Char Schneider* (see fig. 9) was 6 metres in length, 2 metres in width and 3.40 metres high. It consisted of an armoured body resting on two horizontal girders with the necessary bracing. The weight was taken by springs on two bogies on each side, which were carried by the track rollers. The track was actuated by a driving sprocket at the rear, there being an idle wheel at the front. The gear-box was at the rear, the radiator in front. Power was given by a four-cylinder Schneider engine of 60 horse-power. The petrol feed was by pressure. Steering was effected by driving the tracks at different speeds. The whole body formed a box of somewhat peculiar shape protected by hardened steel plate of 11.4 mm. thickness on the walls and 5.4 mm. on the roof. There were various openings with movable shutters for observation, etc., and the door was at the back. In front was a steel prow, or beak, to prevent the machine dipping too much when descending into a cavity. The armament consisted of one short 75-mm. gun, of a maximum useful range of 600 metres, mounted on the right cheek of the bows of the machine which could from its position fire only on the right side and not directly ahead. There was also one Hotchkiss machine-gun on each side firing through a spherical shield mounting. For the gun 90 rounds of ammunition were carried and for the machine-guns 4,000 rounds. One officer, one N.C.O., and four men, of whom two were machine-gunners and one a gunner, formed the crew. The officer drove. The total weight of the machine was 13.5 tons and its useful speed from 2 to 4 km. per hour. It could cross trenches of from 1.50 metres to 1.80 metres in width, and carried petrol for 6 to 8 hours' work.

The *Char St Chamond* (see fig. 10) was a larger and heavier machine. It was 7.91 metres in length, 2.67 metres in width and 2.365 metres or 2.35 high, according to the pattern. It consisted of an armoured body in suitable framework suspended on spiral springs on three bogies on each side, which were carried by the track rollers. The drive was through the rear sprocket. The driving mechanism was petrol-electric and consisted of a four-cylinder Panhard engine of 80-90 H.P. with electric self-starter, a dynamo of 32 K.W. power and two electromotors, one driving each track. Driving was done by a "tramway" control, by which speed and direction

were regulated. This system had great conveniences, for the machine could be driven from either end without effort, but it had the drawback of being somewhat complicated and delicate. The petrol feed was by pressure, and the tanks were two superimposed on the left side and one on the right. The whole body formed a box with a square sloping front without any beak. It was enclosed in hardened steel plate of 11 mm. thickness in the front shields, and 8.5 mm. at the sides and 5 mm. on top. On the roof there were three observation cylindrical *capots* with sides of 11-mm. steel above the commander's and driver's ports. The doors were at the sides. The armament consisted of one 75-mm. field gun, except in the first 175 machines which had a special gun, firing ahead in front, and four Hotchkiss machine-guns, one in front to the right of the gun, one on each side and one on the rear face. For the gun 106 rounds of H.E. were carried and for the machine-guns 8,488 rounds of S.A.A. The total weight, loaded, was 24 tons, and its useful speed on the flat 4.5 km. per hour. It could cross trenches up to 2.50 metres in width in good soil. The petrol carried was enough for from 6 to 8 hours. The crew consisted of one officer, one N.C.O., two gunners, four machine-gunners and one mechanic, or nine in all.

During Sept. the first tank of each type arrived at the training centre, where a considerable number of officers and men from different branches of the Service had already collected for preliminary individual instruction. An additional training centre for the formation of units was established at Champieu, and also a depot for the assembly of *matériel* at Cercottes, near Orleans. It was then decided, also to create the new "*Artillerie d'Assaut*" and the charter of this organization may be said to date from the 30th of that month. Col. Estienne was promoted to the rank of general, and was appointed "*Commandant de l'Artillerie d'Assaut aux Armées*" and representative of the commander-in-chief in tank matters with the Ministry of Munitions, which department had been created and taken over tank production. In Oct., with the arrival of more machines of both types, the *Artillerie d'Assaut* started on its career. It seems that the use of the British tanks at Cambrai, which had been deprecated by the French beforehand, and criticized for the reasons already stated, may have stimulated the French to press on with their own service, though what had been looked upon as the supreme factor of surprise had been discounted.

FIG. 10.—French Char St. Chamond.

The work of preparation, including training and equipment, continued throughout the winter, in preparation for the offensive to be undertaken in the spring of 1917. On March 31 1917, the organization of the *Artillerie d'Assaut*¹ was as follows: The tactical unit, under a captain, was the *groupe*, which was divided into four batteries, each consisting of four tanks. A *groupe*, therefore, comprised 16 tanks with a special "command" light tank (Renault). For a Schneider tank *groupe* the establishment was 18 officers and 92 other ranks, for a St. Chamond tank *groupe* 18 officers and 106 other ranks. A *groupement* consisted normally of four Schneider or three St. Chamond *groupes*, but was not rigid. For repair work each *groupe* had its own workshop and a *Section de ravitaillement et de réparations*.

¹ Why this arm was ever called "artillery" is not clear. Its closer connexion with, and resemblance to, infantry was recognized later, and the names of the elements of the organization for the light tanks followed those of the infantry, e.g. battalion, company, etc.

(S.R.R.), of 1 officer, 111 other ranks, was allotted to every 10 *groupes*. There was for the whole unit a *Section de pare*, or repair park, similar to that of the Mechanical Transport Service. This was found necessary so soon as tanks had been delivered in any number, owing to the amount of tuning-up, minor repair work and even alterations which had to be done.

Numerous faults at once developed in these entirely new machines (as had been the experience of the British), but thanks to the time available before they went into action, certain defects were discovered and remedied. The first was that some parts of the machines wore out very quickly, necessitating the maintenance of a very large stock of spares. The thickness of steel plate where vertical was not proof against the German "K" bullet, and it was found necessary to add an outer plate of 5.5 mm. to the vertical armour of the Schneider machines, and 8.5 mm. to that of the St. Chamond machines. On the whole the defects discovered in the Schneider tanks were not such as to give reason to suppose that they would not be able to go into action in the spring; but those of the St. Chamond were more serious. The design was found clumsy and the machine liable to ditch. In addition to breakdowns in the power system and failure in details, there was a lack of rigidity in the whole machine, and the tracks of the first machines were too narrow.

Delivery of both types was extremely slow, especially of the St. Chamond machines. At the end of March, though personnel for 15 of the latter was ready, there was not one machine serviceable. At this time, on the eve of the great 1917 offensive of which so much was expected, the *Artillerie d'Assaut*, instead of being in possession of the 800 tanks which were to have been ready by the previous autumn, had received not more than 208 Schneider and 48 St. Chamond machines. There were for this operation, therefore, only 8 fully and 2 partly trained *groupes* of Schneider and 1 of St. Chamond tanks, and not 40 *groupes* as originally contemplated, and of the 160 Schneider machines only one had been fitted with the extra bullet-proof protection. In view of the diminution of the tank force from what was expected to be available, and with the example of the result of the action of the British in the previous Sept. before it, the French High Command had grave doubts whether to make use of tanks in the coming operations or to wait until there should be sufficient to exercise a greater influence. It was finally decided to throw all possible weight into the attack.

April 16 was the baptism of fire of the French tanks, in Gen. Nivelle's unsuccessful attempt to break through the German line along the Chemin des Dames, E. of Craonne.

Eight Schneider *groupes* cooperated with the French V Army. They were divided into two parts of three and five *groupes* respectively. One party did not succeed in crossing the German line, though a few machines reached it, and it suffered severely from the enemy's guns posted on the Craonne Plateau. The other party succeeded in crossing the enemy's second line, but were not followed up by the infantry, owing to the German machine-gun fire. Two Schneider *groupes* and one St. Chamond *groupe* allotted to the French IV Army for employment on the 17th were not thrown into the fight, as the German artillery observation posts were not first captured by the infantry—a lesson of the action of the 16th. The offensive failed; and though the new arm showed the utmost devotion and gallantry, and its intervention saved many lives, it did not achieve the success that was hoped. But the conditions were almost as unfavourable for the employment of tanks as they could be, and the tactics employed were not those urged by those responsible for the new arm. The attack was not a surprise, being preceded by a heavy bombardment, which, however, did not succeed in overcoming the German artillery, and was made in broad daylight, without any smoke-screen, against a position which permitted of direct observed artillery fire against the tanks both when approaching and when they reached the enemy's positions. The plan, also, in which certain infantry units had been trained to cooperate, was that the tanks were to attack the German third defensive line after the infantry should have gained the first and second, and were not to advance until after this had been achieved. The Germans, who were prepared for the attack, therefore, had even additional time before the tanks appeared, and the result was that their guns caught many of the machines in column before they deployed.

The machines themselves showed certain faults—they were deficient in speed and climbing capacity, the latter defect being accentuated by the fact that since the Somme the Germans had increased the width of their trenches. They also proved, as was known before would be the case, vulnerable to direct hits of H.E. shell, by which many machines were set on fire. Amongst other points of design in which modification was found necessary was that of isolating the petrol tanks from the interior of the machine, improving the means of communication, the power of observation, the

ventilation, and various details of mechanism, and of widening the tracks. On the whole the Schneider machines stood the trial best.

In the next tank attack, carried out on May 5 by the VI. Army, the battle of Laffaux Mill, the three *groupes* employed advanced with the infantry with marked success, especially in the case of the Schneider machines. The counter-battery work of the French was good and the enemy observation posts were destroyed or masked; and the tanks did not remain too long in advanced positions where the infantry were checked.

For nearly six months the tanks did not again go into action. During this period great efforts were made to remedy the defects disclosed, to expedite the delivery of machines, which was much in arrears, and of spare parts, the demand for which (as in England) had been found very greatly to exceed any anticipations, and to augment the establishment of repair units. In preparation for the next operation great care was taken in the training of infantry with the tanks in attack and in tank tactics generally. On Oct. 23 five *groupes* of tanks took part in the battle of La Marnaison along the Chemin des Dames. Their assistance was most valuable.

Owing to previous heavy rain, and the bombardment which had continued for six days and six nights, the ground was extremely difficult, and in the centre the tanks were not of so much help in the first phase of the attack as later. This state of the ground and the lack of surprise again disheartened to a great extent the preparatory training undergone by the units of the *Artillerie d'Assaut*. The practice which had been carried out beforehand with the attacking infantry, however, proved of great value, as did the work of the special unditching sections. The ground had been carefully reconnoitred and aerial photographs supplied. The Germans relied on this occasion more on their advanced field guns for defence, and had also organized numerous special machine-gun posts furnished with plentiful supplies of armour-piercing ammunition. But owing to the counter-battery work of the French the tanks were not so much damaged by the German guns as in April, in spite of the fact that the attack was not a surprise. Two days later some St. Chamond machines again operated with success.

Apart from the projected light tanks, the necessity for an improved medium tank had been realized before April 1917, and the subject was under consideration throughout the year. The main directions in which the April offensive showed improvement to be necessary were the desirability of mounting the gun in a turret to give all-round fire, of mounting a 75-mm. field gun in place of the shortened 75, and of increasing the size of the tracks and the power of the engine. Designs for a new medium machine (C.A. 3) were prepared in Aug. 1917, but were abandoned after the battle of La Marnaison because the further improvement then found desirable, i.e. the provision of 6 to 7 H.P. per ton weight, a trench-crossing capacity of 3 metres, and an ability to climb ahead or astern, showed that the designs were already out of date, and would be more so by the time the machines could be made. At the end of Oct. it was decided to suspend the construction of an improved type of medium tanks and to concentrate on that of the light machines; and in Dec. the idea was finally dropped. The question of providing heavy tanks was taken up at the end of 1916 as a result of the operations of the British machines in Sept., and in order to have available a machine which would be complementary to the light tanks it was hoped would be made. A project was put forward for a heavy tank weighing 38 tons to carry a 105-mm. gun, but its execution was postponed in view of the demands that might be made for other machines. Two experimental heavy tanks, one with mechanical and the other with electrical transmission, were tried, and it was decided to investigate in the direction of still heavier machines.

In regard to the type which will always be especially associated with the French, the *Char leger*, or Renault tank, first suggested by Gen. Estienne in July, and for which designs were prepared in Nov. 1916, the commander-in-chief in that month expressed his desire for 1,000 of such machines. But whereas those responsible for supply had, in the case of the medium tank, pressed forward the construction of one type, the St. Chamond, without military approval of the design, in the case of the Renault every obstacle seems to have been placed in the way of manufacture of this machine, for which army H.Q. and the *Artillerie d'Assaut*

were pressing throughout the winter, though various trials were made. In March 1917, the demand of army headquarters was increased, being based on the requirements for an offensive on a 100-km. front. This entailed the production of 3,000 light, 400 medium (improved Schneiders) and 150 heavy tanks. In May an order was given for 1,000 Renault machines in addition to 150 which had been ordered in March as "command" tanks. Discussion as to design, armament and manufacturing facilities and trials continued during the summer of 1917. In Oct. it was settled that in addition to the 1,150 already on order, 2,380 more should be made, or 3,250 in all, the work being distributed between four French factories, the whole to be delivered by the end of July 1918. Of the total, 1,000 machines were expected to be ready by March 31 1918, for the contemplated offensive in the spring, and 1,000 were to be manufactured in the United States, of standard American parts and equipped with Liberty engines. The decision to devote so much money as this entailed and so much of the manufacturing power of the nation at a moment when the demands for munitions of war of other kinds was at its height illustrates the importance now attached to the new arm. The British success at Cambrai seems to have had considerable effect in influencing those who were still sceptical of the value of the tank and of the wisdom of relying on it for future operations. In Jan. 1918 a supplementary order was placed for 470 machines, the final total figure fixed for production in France being 4,000, divided into 1,000 armed with machine-guns, 1,830 with the 37-mm. gun, 200 signal tanks, and 970 for a reserve armed with the 75-mm. gun.

The Renault tank differed greatly from the Schneider and St. Chamond machines. Not only was it considerably smaller, but the tracks were outside the body and not underneath it and extended to a considerable distance in front. Its total length, without the movable tail, was 4.100 metres; its breadth 1.740 metres, and its height 2.140 metres. The body was supported on hollow longitudinal girders by a hinge arrangement at the rear end and suspended on powerful springs in front so that the front of the frame and body were capable of relative movement. Each girder was carried by springs on four bogies supported by wheels running on the tracks. The idle track pulley in front was of larger diameter than the driving-sprocket at the rear and this and the projection of the tracks gave the machine a greater grip in climbing over obstacles. The upper portion of the track ran in spring guide rollers which were arranged to regulate the track tension automatically. The interior of the tank consisted of a driver's compartment in front and the engine-room behind. The crew comprised two, one officer or N.C.O., who was also the gunner, and one man who was the driver. The driver was seated; and also seated, or standing, behind him was the gunner, with his head and shoulders in the turret. The latter revolved on ball-bearings which allowed of all-around fire, and was furnished with a lock and a door at its back. The whole of the machinery, engine, radiator, clutch, transmission gear and petrol tank were in the engine-room, separated by a steel bulk-head pierced by openings closed at will from the driver's compartment. Power was given by a four-cylinder Renault engine of 35 H.P., with the usual transmission. Steering and control could be done by one man. Protection consisted of hardened steel plate 16 mm. thick for the vertical portions (proof against the armour-piercing bullet) and 8 mm. for other parts. The armament was either a 37-mm. Puteaux semi-automatic gun, or a Hotchkiss machine-gun; and 240 rounds including 40 rounds of case shot, or 1,830 rounds of S.A.A. were carried. Fully loaded the female weighed under 6½ tons and the male just over 6½ tons. There were four speeds ahead and astern giving to the tank a maximum speed on the flat of 7.78 kilometres. It could climb slopes up to 45° and span openings up to 1.80 metres in width, in which it was assisted by the movable tail. This was the machine upon which the French relied for the operations of 1918. The question of the provision of Renault wireless signal tanks was taken up in May 1917, and a machine capable of sending and receiving wireless messages was constructed.

In the autumn and winter of 1917 the reorganization and training of the *Artillerie d'Assaut* continued with a view to its expansion. In addition to the medium tanks still being delivered, it was expected, by March 31 1918, to receive 800 of the Renault tanks then due. The establishment of the *Artillerie d'Assaut* was tentatively fixed as follows:—four *groupements* (16 *groupes*) of Schneider tanks, with four repair sections; four *groupements* (12 *groupes*) of St. Chamond tanks, with four repair sections; 36 companies of Renault tanks; one *groupe* depot for Renault tanks; one salvage *groupe*; three park sections. The number of Renault companies was fixed at 30 before the end of the year.

The organization of the Renault tanks, which were regarded as an infantry arm, was to be by sections, companies, battalions and later by regiments and brigades. A company comprised three sections of five tanks each and an *échelon de combat* of 10 tanks (of which one was a wireless signal tank),¹ or 25 machines in all. A battalion contained three companies of 75 tanks. Changes were made in the administration, and Marly-le-Roi was given up as a training centre, two army group-training centres being established at Mailly-Poivres and Martigny, the training facilities and auxiliary services generally were increased and elaborated, and the relation of the *Artillerie d'Assaut* to the Ministry of War was defined and simplified. All these preparations were carried out with a view to the coöperation of the tanks in the French offensive in the spring.

When the German advance on March 21 1918 wrested the initiative from the Allies, amongst other results it upset all the plans carefully worked out for the French tanks. Instead of taking part in mass in a great offensive, as intended, whatever tank units existed had now hurriedly to be collected and thrown into the defence. The factor ruling the speed of the creation of the service had all along been the rate at which the *matériel* was delivered. This, for various reasons, was always much behind the scheduled time arranged. On March 21 the medium tanks in a serviceable state fit for immediate use amounted in number to 245 Schneider and 222 St. Chamond, or 467 machines of an obsolescent type, and of the new Renault tank 1 machine ready for action, with the army. (By the beginning of April over 400 had been turned out by the factories. But these were made up of training machines without armament or armour, pattern machines, machines issued to the American army for training, and those under test.) Moreover the approach of the Germans necessitated the hurried evacuation of the tank centre and main park at Champlieu. And so, not only was the new arm, still in its early infancy, forced to face an entirely fresh situation with improvised measures, but part of its organization was suddenly torn up almost before it had taken root. Great efforts were made both to assist in coping with the immediately urgent necessity of checking the enemy's advance and to prepare for subsequent action. Champlieu was reoccupied in the beginning of April, when the progress of the Germans to the north was checked, but a central reserve park farther from the front, near Fontainebleau, and three others were established.

Operations during April and till the end of May were confined to the medium tanks, which alone were available and mobilized. Four *groupements* of Schneider machines were allotted to the III and I. Armies, joined later by three of St. Chamond machines. All the actions now undertaken were, as was the case with the British tanks, of the nature of minor counter-attacks, and not such as the tanks were best suited for. They took place, on April 5, at Grivèsnès; on April 7 at Sénécât; and on April 8 at Cantigny, the last being in coöperation with the American troops. The most successful was the last, in which the action of tanks had been legislated for. The artillery bombardment was short and portions of ground were left unshelled to allow of the passage of the tanks. Though not actually fighting, the tanks were at this period continually being moved about in readiness, and to save wear and tear the system was adopted of transporting them by road on special "tugs" drawn by caterpillar tractors.

On May 31 the Renault machines received their baptism of fire on the E. of the Forest of Retz. Three battalions of these machines now ready were allotted to the VI. Army, and were brought up by train, on lorries and on tugs. Six sections had to be flung into the fight. Without previous reconnaissance or any liaison with the already exhausted Colonial infantry, who had never seen a tank, they had practically to make a cavalry charge in broad daylight, without a smoke-screen, across a mile

¹Owing to delays in manufacture and difficulty in technical training the first wireless signal tanks did not take the field until July 1918, when after some practice they were found of great value. As has been stated British tanks were fitted with equipment and trained operators ready for the field in July 1916.

of open plateau under observation of captive balloons and without effective support from their own guns. One condition favoured their action; their attack was a surprise.

Though the tanks succeeded in clearing the enemy out of their positions, their success had no tactical result, for the infantry could not follow up and consolidate the ground gained. But they caused panic, and inspired a nervousness and hesitation amongst the Germans which was invaluable at the moment. This and their subsequent actions carried out during June served to prevent the enemy from penetrating into the forest.

Meanwhile, four *groupements* of medium tanks led and greatly assisted Gen. Mangin's counter-stroke at Méry-Belloy on June 11 against the flank of the German salient between Noyon and Montdidier, by which the enemy's progress toward Compiègne was arrested. The tanks played a great part in this operation which had such strategic importance, but this action was the high-water mark in the career of the medium tanks, for they were becoming worn out and were gradually replaced by the new and more efficient Renault tanks as the latter were produced.

By July considerable progress had been made in organizing and equipping fresh units, and the *Artillerie d'Assaut* was able to coöperate on a large scale in the battle of Soissons, Gen. Foch's decisive counter-stroke of July 18 and following days, against the German salient formed between Château-Thierry and Reims. This was the vindication of the French tank arm. To the X., V., and VI Armies were allotted respectively six, one, and one *groupements* of medium tanks, and to each three battalions of Renault tanks, or a total for the operations of eight *groupements* of medium and nine of Renault tanks. The battle, which lasted from July 18 to the 23rd and 26th, so far as the tanks were concerned, formed a turning point in the war. The entire operation was based on the action of the tanks, every available machine was thrown into the fight, and they were given a chance of showing what they could do.

The tactics employed were those which had been urged all along by Gen. Estienne and M. Breton, and were a repetition of those initiated at Cambrai. The attack opened with the advance of a mass of tanks without preliminary bombardment, as it happened, in a slight fog, and was a complete surprise. Similar tactics on a smaller scale were made use of again after the first day, but on the 23rd the tanks suffered severely from the enemy's guns. Two battalions of Renaults acted with the VI. Army east of Reims on July 16-17, and cooperated with two medium *groupes* with the IX Army on July 18 near the Marne, and some with the British on July 23 near Espilly. In these operations, especially the main attack on July 18, the tanks achieved what it had been claimed they would if properly used. On July 30 the commander-in-chief issued a special Order of the Day to the *Artillerie d'Assaut*—"Vous avez bien mérité de la Patrie," whilst Gen. Estienne was made a commander of the Legion of Honour and promoted general-of-division.

The battle of Soissons had a great effect on succeeding operations. It established the value of the tanks beyond all doubt, inspired enthusiasm in all that concerned the arm and expedited the manufacture of the machines and the training and organization of new units. Without giving even the list of actions in which the tanks took part to the end of the war, it can be said that the infantry now clamoured for their assistance, in spite of their faults and failings, and they were employed whenever possible. They were asked for by the commander of the VI. French Army when transferred to Flanders, and on Sept. 30 and several days in Oct. were in action. Some were also sent to Salonika. Out of the 120 days between July 15 and Nov. 11 they were used on 45 days, and the casualties suffered amounted to 300 officers and 2,300 other ranks. During 1918 3,088 individual engagements were fought: 3,140 by Renault, 473 by Schneider and 375 by St Chamond tanks. Toward the end their actions amounted to disposing of the enemy rearguard machine-guns which continually held up the infantry.

By Aug. the machinery of production and training had been so improved that it was found possible to turn out one battalion of Renault tanks (75 machines) per week, which implied a vast increase in the whole of the rear organizations, which were now of a capacity for the continuance of the tank effort on a greater scale in 1919. As in England the production of tanks had become an industry. Though the construction of medium tanks had been abandoned, Gen. Estienne's opinion as to the necessity for heavy machines had not changed from the time in Feb. 1918, when he had asked for 900. But the same influences that had in 1917 retarded the introduction of the light tank were now adverse to the contemplation of heavy machines. To provide such machines an Inter-Allied factory was

established, but this was not completed before the Armistice. In Oct. negotiations which had been carried on with the British Government resulted in the promise of some Mark V. and Mark V. Star tanks. Of the latter, 77 were handed over in November.

In Aug., at the instance of Gen. Foch, an Inter-Allied tank school was opened in France. It was equipped with a staff of French and British instructors and various types of British and French machines. This school was for the interchange of views and the establishment of a common basis for tactics and staff work concerned with tanks.

The reliance that had come to be placed on the *Artillerie d'Assaut* can be gauged by the fact that in Oct. 1918 its actual strength in the field amounted to 18,023 of all ranks.

Since the war the French have been continuing their development of cross-country machines. The construction of a very heavy armoured tank was in hand in 1921, while a much lighter machine, the "Kegresse," of Russian invention, had been tried. It consists of the substitution of small rubber tracks for the rear wheels of a motor-car. It is light, cheap, can travel on the flat at a speed of 15 to 20 m. per hour, and can cross any country over which cavalry can pass. An amphibious tank propelled on land by tracks and on the water by a screw has also been tried successfully.

AMERICAN TANKS

Though the tank had not accomplished much in the way of results by the time that the Americans came into the war, in April 1917, its military potentialities were at once appreciated by them, while its mechanical side appealed to their national genius. But hostilities did not continue long enough for them to bring their vast resources to bear on its development. The Americans lost no time in inquiring into the subject, and at once requested information as to designs, etc. At this time there was some doubt as to whether the tanks should not be taken up by the American Marines, but the final decision was in favour of the Army. In June the commander-designate of the American Tank Corps, Col. Rockenbach, arrived in France, and an officer was detailed to inquire into the technical aspect of the tank arm. An Inter Allied Tank Bureau was also established. In Sept. a scheme for an American Tank Corps, to consist of five battalions of heavy tanks and 20 of light tanks, was approved, and in Oct. an expert technical officer reached England to consider further the question of development.

The question of the provision of machines and spare parts, which had proved such a difficulty with the British and French, was also taken up. It was realized that in matters of design, it would be best for the Americans to profit by the experience of the British and French, whilst relying, as far as possible, on their own resources for *matériel*, and it was decided to adopt a heavy tank of the British type, and a light tank of the French Renault type. As a result of consultations between the British and French Ministries of Munitions and the American commander-in-chief as to joint production, an Anglo-American commission was appointed in Dec. to deal with the question, and in Jan. 1918, an agreement was signed by the two Governments for the manufacture of tanks in France. It contained, amongst others, the following main provisions:—that a factory capable of producing 300 tanks a month, and of being extended to turn out up to 1,200 a month, should be erected in France at the expense of the two Governments, that 1,500 machines, or more if required, should be made during 1918; that, in broad terms, in accordance with national facilities for production all the machinery should be of American and the structure and armament of British manufacture, the armour plate being of American steel, and that the first 600 tanks should be allotted to the Americans, and the remaining output as agreed upon, including sale to the French. The type of machine was to be the "Liberty" or "Allied" tank, which was the British Mark VIII. machine equipped with the Liberty aero-engine.¹ It was decided during the summer that an additional 1,500 of these tanks should be built in the United States, as well as several thousands of Renault machines. The scale of this programme shows what importance was attached to this arm by the Americans. The site chosen for the factory was Neuvy-Pailloux, near Chateauroux, and work was started there in the spring. But the building was not completed till Nov., so this scheme of joint production did not actually come to fruition,

¹ The first Liberty tank of British structure and American mechanism was assembled and successfully tried in America in Nov. 1918. One machine was constructed in England by the end of 1918.

and although preparations were made for a vast output of machines in America, by the Armistice the manufacture had only recently reached the stage of production and only twenty odd American-built Renault machines had reached France. All the tank operations in which the Americans took part were therefore carried out with British or French machines.

As to *personnel*, in Feb. 1918, 500 volunteers from the American army assembled at Bourq in France for instruction, and from the next month onwards three companies of soldier mechanics assisted at the repair depot at Bourron. The establishment of the American Tank Corps was increased in May to 15 brigades (five per army), each consisting of one heavy and two light battalions. Owing to the lack of machines in America it was necessary to send the units of the Tank Corps for training with the machines to England and France, a camp being established at Bovington, in Dorset, the British tank-training centre, for training the heavy tank units, and at Bourq for that of the light tank units under French supervision. In addition to 25 instructional machines, with accessories and spares, previously supplied, 141 Renault tanks, the complement of two light battalions, were handed over in Aug. to the Americans. Two battalions were at once mobilized and took part in the attack of the St. Mihiel salient by the American I. Army on Sept. 12.

The entry into action of these units was somewhat disappointing. The tanks had to travel far from their positions of assembly to the battle, and on the first day they operated over such difficult ground that they did not catch up with the infantry, who were able to move forward rapidly owing to the comparatively feeble resistance of the enemy. On the second day they were unable to obtain petrol, and on the third day they did not have much fighting, but took a number of prisoners. The machines were practically undamaged by the action. Their next operations were with the French in the Argonne, where they were of considerable assistance. From this time until the middle of Oct., when they were re-formed into one company, they were continually at the disposal of the infantry commanders, but did not often take a cooperative part in action, though they travelled miles, being used mostly for reconnaissance and for attacks against strong points which had checked the infantry. After that date they accompanied the American forces in the advance right up to the end. One heavy tank battalion which had been trained in England took the field on Sept. 29 with the American II. Corps, in the attack on the Hindenburg line. On this occasion ten tanks were destroyed by running into an old British minefield, and the American infantry here suffered severely from the German machine-guns. On Oct. 8, the battalion cooperated most usefully with the American II. Corps, and again on Oct. 17, when the River Selle was crossed. Finally they assisted the British on Oct. 23 in the neighbourhood of Le Cateau. This ended the operations of the units of the Tank Corps.

The chief characteristics of the action of the Americans in regard to tanks was their quick appreciation of the value of the arm. But the extent of the preparations made for a continuance of the struggle in this as well as in some other directions prevented a greater part being played by the American tank forces in the field. Had the war continued it would have come into play with overwhelming effect.

Since the Armistice the Americans have pressed on with the development and application of the caterpillar track system for road and cross-country transport generally. Most of their efforts in this direction have been concentrated on the "motorization" of artillery traction, and a considerable amount of literature has been published foreshadowing the future ideal as elimination of the horse for military transport purposes. Experiments have been and are being carried out with different types of self-propelled vehicles on the caterpillar track, and combined wheel and track principles. One machine of the latter type recently covered 251 m. in 17 hours. Of fighting tanks, the Mark VIII. of 35 tons is still the standard heavy machine, but experiments are being made with modified Renault and Ford light tanks, and a water-crossing machine. On the whole the Americans seem to be greatly impressed with the part that will be played by machines in the warfare of the future and have made great steps in applying track propulsion to military uses.

GERMAN TANKS

In spite of rumours, the first appearance of the British tanks came as a complete surprise to the Germans. In Dec. 1913, and again toward the end of 1914, proposals had been made in Germany for an armoured automobile on caterpillar tracks; and in the summer of 1915 some experiments in this direction had been carried out, but no steps were taken to proceed with the idea. In Oct. 1916, after the appearance of the British tanks, of which they temporarily captured one, the question of constructing similar machines was taken in hand by a special commission, and drawings were prepared. Construction, however, was postponed, owing to the lack of coal and steel, and to the economic conditions generally. H.Q. appears then to have become doubtful as to the necessity for these weapons, and did not give this service

first priority of urgency. This was actually not done until the summer of 1918. This lack of interest or apathy on the part of the Germans came as a surprise to the Allies, for it was anticipated that so soon as the secret was out the enemy would use every endeavour to copy and improve on the machine and press on with mass production so as to make up if possible for the start the Allies had gained. For a long time opinion in Germany remained divided as to the value of the weapon, partly owing to the mechanical imperfections of the original Allied machines and partly owing to the manner in which they were first used, especially during the summer of 1917.

Nevertheless, manufacture of a tank, known as type A 7.V., apparently the result of the deliberations of the commission already referred to, was commenced in the spring of 1917. Only 10 of these machines were ready for the offensive in March 1918, whilst not more than 20 were completed by the end of the war. Designs for a heavier type, also, were started about the same time, of which the first model was to have been ready in Dec. of that year, but it was still unfinished at the end of the war. Experimental construction of a small light tank was also commenced, and orders for these machines were placed in the summer of 1918, to be ready by the spring of 1919. This contract, also, was cancelled at the suspension of hostilities.

The French attack at La Malmaison in Oct. 1917, and then the British attack at Cambrai somewhat changed the aspect of affairs. The British tanks captured by the Germans in their counter-attack after the latter action were collected at Charleroi and repaired, and the question of production in quantity of a German tank based on the British type was considered, only to be dropped, owing to the shortage in man-power. In Jan. 1918, the first "Sturmpanzerkraftwagenabteilung" (Tank Section), of five German A 7.V. machines, was formed and brought with its auxiliary transport up to the western front for training. The captured tanks, also, were organized in sections of five machines. The personnel establishment was on an extravagant scale, no fewer than 176 of all ranks being allotted to a section of German machines, and 140 to a section of captured British machines, as against the British establishment for a similar section of 41 of all ranks. In all, three sections, comprising 15 of their own tanks, and six sections comprising 30 captured machines, were used by the Germans in 1918. Some of the latter were re-armed with 5.7-cm. Russian guns.

FIG. 11.—German A 7.V. Tank.

The description of the A 7.V. machine (see fig. 11) is as follows:—weight, 32 tons; length, 7 metres; width, 3.2 metres; height, 3 metres; armament, 6 machine-guns and one 5.7-cm. gun; protection, armour 30 mm., 20 mm. and 15 mm. thick; crew, 1 officer, 15 other ranks (mechanics, gunners, machine-gunners); power, two 100-H.P. Daimler engines, each driving one track; climbing capacity, trenches of 2.5 metres width. The German tank was a clumsy machine and a bad climber, owing to the underhung tracks. It was powerfully engined and its tracks were carried on spring bogies which enabled it to cover 8 m. per hour on the flat. The thick armour was proof against armour-piercing bullets at short range and also against light-field-gun shells; but the joints between the thick plates rendered the crew liable to bullet splashes, which was a serious defect.

The Germans used their tanks on nine occasions in 1918, commencing with their advance on March 21, the most successful action being when they captured Villers-Bretonneux on April 24, 12 German machines coming into action on this occasion. The result of the appearance against the British of hostile tanks, especially on this date and later, on Oct. 8 in the Cambrai sector, when 15 captured British machines were used, was sufficient to confirm their great moral effect and the feeling of helplessness engendered in infantry by them. It showed that it was not only the Germans who could not stand up against the attack of these machines, for the British infantry fell back on the report of the appearance of German tanks as did the German troops at each appearance of the Allied machines, when the Allies were pressing forward. The German tank tactics do not appear to have been very thoroughly thought out, and consisted mostly of "mopping up." This is probably due to the smallness of the number possessed by them and the improvised nature of the arm. Moreover, the belief in their own powers of the members of the tank units must have been somewhat shaken by the official propaganda campaign which had been carried out for months by the High Command to discount the effect of the British and French machines.

According to one authority, the reasons that the Germans did not during 1917 whole-heartedly take up the organization of tanks in large numbers for their great effort in the spring of 1918 were that when they first became aware of their existence it was too late to carry out the successive operations of design, experiment and manufacture in bulk, and that owing to lack of raw material and shortness of man-power the manufacture of the machines would have entailed the cutting down of the production of other war material. There does not seem to be much force in the first argument, if it be remembered that 80 British tanks were ready equipped in the field within 13 months of the receipt of the specification by the designers, and this without any existing machines to serve as patterns. All along, the attitude of the German High Command seems to have been that of the staff and not that of the troops, and great endeavours were made to inspire the latter with the official view. Though official disbelief was seriously shaken by the surprise of Cambrai, the success of the German counter-attack 10 days later was used, illogically enough, to discount the effect produced by the previous assault by tanks. There was, however, a general and absolute revulsion of feeling after the great French success on July 18 1918, and the British actions of Aug. 8 and 21, which almost amounted to panic at H.Q., and converted both critics and military authorities. There were numerous articles in the German press during Sept. severely censuring the High Command for having neglected to provide tanks for the German forces and to undertake measures against the Allies' machines. Popular opinion became so strong that a stormy debate on the subject took place in the Reichstag in the following month, when the Minister of War made an apology for the neglect to equip the German troops with this weapon. There is no doubt as to the opinion of the German army and the nation on the subject of tanks from then on to the end of the war. For months after the cessation of hostilities the tank was called "*Deutschland's Tod*"—"the Death of Germany."

ITALIAN TANKS

A great part of the theatre of war in which the Italians were operating for so long was too mountainous for tank operations, and the question of the organization of a tank arm was not taken up by Italy until 1918. Manufacture of tanks was then started, and by the time the war came to an end one or more Fiat machines were ready to take the field, but none was actually used.

ANTI-TANK DEFENCE

The tanks used by the British and French during the war were designed to be bullet-proof only, not being strictly speaking "armoured," and were vulnerable to gunfire. The best active defence against them since they were moving targets, was the direct fire over the sights of as light a Q.F. piece as could insure penetration. Any field gun in use during the war, or light Q.F. guns of the "Pom-Pom" type, were sufficient. But as the tanks were mobile and could attack at any spot, often by surprise, to attempt to meet them with special or stationary guns in position would have entailed the distribution and locking up on the mere chance of attack of a prohibitive amount of artillery. The alternative was the provision of suitable guns themselves protected and capable of movement across country, so that

they could be concentrated speedily when and where required. In other words, the correct reply to the tank was a type of male tank capable of rapid movement. The Germans eventually produced this reply in principle, in their own A.7.V. tanks, and by re-arming the male British Mark IV. machines and those of the French Schneider and St. Chamond (gunned) types which they had captured. This took place, however, too late and on too small a scale to influence the course of operations. Technically, also, the German machines failed in mobility across entrenched country. In order to effectively attack the German tanks by gunfire armour-piercing shell was required, for they were protected by hardened armour up to 30 mm. (1.2 in.) in thickness.

As the Germans were forced by circumstances to develop anti-tank defence, from which duty the Allies were almost entirely spared, the measures they adopted are here reviewed. Their action, which consisted for a long time largely of injunctions to the infantry not to lose their heads in the event of a tank attack, suffered from the continual inability or unwillingness of the High Command to take this weapon seriously, in spite of the lesson of Cambrai of Nov. 1917, till after the French attack on July 18 1918. In Sept. 1916 the Germans of course had no special means of defence against the tanks, of the existence of which they were ignorant, and these machines had an opportunity on their first appearance never to be repeated. After the Somme battle certain measures of anti-tank defence, seemingly based on a misunderstanding of the nature of the machine, were undertaken, mostly in the direction of obstacles, such as pits, etc., in roads, and indirect artillery fire. After April 1917, it was discovered that neither the British nor French tanks were proof against the "K" armour-piercing bullet with which the troops had been equipped for use against loop-hole shields, and considerable reliance was placed on this fact. But this discovery did not help the Germans much, the tanks (Mark IV.) used in the next action by the British having had this to a great degree remedied. During that year the value of gun defence against tanks was to some extent realized, attention being mostly given to indirect fire which of all kinds is least effective against moving targets. A certain number of special direct-fire, anti-tank guns often in concrete shelters, were emplaced along the front. But not much attention was paid to the use of direct fire from field artillery normally in the sector attacked. This was not so on the occasion of the French attack on the Crivonne Plateau on April 15 1917, when the guns of the defence of all kinds did great execution among the French machines. At the battle of Cambrai again, some of the German field artillery were most effective against the British machines, one well-concealed gun served by a German major putting 16 tanks out of action.

During the period of preparation for the 1918 offensive the anti-tank rifle, which was a definite step forward, was evolved. This was a heavy, single-loading rifle of 530-mm. calibre, 5½ ft. long, weighing 36 lb., firing armour-piercing pointed bullets. The bullets penetrated the tank plates, though they did not necessarily place a tank out of action, but the weight of the weapon and its recoil hampered free employment by the infantry.

It was after July 18 and Aug. 8 1918, that the German High Command awoke to the danger threatening the German defensive, and indeed issued almost panic instructions. Special anti-tank defence officers were appointed to the different formations; guns were brought up to the front line and emplaced for action against tanks alone; and sections of reserve batteries were allotted to this duty, whilst all batteries (including howitzers) were to take up positions from which they could engage tanks by direct fire. The most efficacious of these precautions was the employment of the mobile guns of reserve batteries which were not so likely to be knocked out by barrage fire as those in positions closer to the front. Tanks became a bugbear, all sorts of precautions in the way of signals to notify their approach were taken, such as the installation of rockets, sirens, Klaxon horns; and permanent alarm posts were established. The passive forms of defence employed were obstacles in the roads and entrances to villages, such as steel palisades, concrete blocks set sufficiently

close together to prevent the passage of tanks and of sufficient height to be unclimbable, and mine craters. In some cases elaborate *chevaux-de-frise* were erected across stretches of the front; "booby-traps" such as tank-pits were laid and certain areas in the later stages of the operations were flooded. Mines were employed to an increasing degree, sometimes in large minefields. It does not require a great amount of explosive to damage a tank, and the mines laid by the Germans were usually electro-contact, or mechanical "tread" mines, which were fired by the weight of a tank passing over them, the charge being a gun or trench-mortar shell. But land mines have the drawback of being dangerous to those who use them, and the greatest damage done to tanks by mines during the war was to the British machines manned by Americans in July 1918, by a British minefield prepared during the retreat in March and forgotten. On the whole, all these artificial obstacles proved a failure, for they could not be continuous, and could be avoided by a cross-country vehicle.

The Germans finally took the obvious step of producing a large-calibre, high-velocity machine-gun firing heavy armour-piercing bullets. This weapon, if fairly mobile, would have been an effective reply to the tank had it been introduced sooner. It was known as the "Tuf" (*Tank und Flieger*), was of 13-mm. calibre and could fire 200 bullets, said to be capable of piercing 30 mm. of hardened steel, a minute. Great efforts were made to produce it quickly and to keep its manufacture secret. Six thousand were to have been ready by April 1919, but by the Armistice none was in the field.

The greatest physical obstacle to the advance of tanks—one form of defence—experienced during the war was mud, and this was intensified by the concentrated and prolonged artillery fire which was generally carried out by both sides. In dry weather this rendered the ground almost impossible to negotiate and in wet weather made it absolutely impassable by any machine moving on the surface of the ground. This was well exemplified during the third battle of Ypres in 1917, when the Germans could not have arranged a better defence against tanks than the morass created in the low-lying battlefield by the British guns. Here the conditions were such as to render futile the employment of tanks which was attempted. The best anti-tank defence beyond this half-natural, half-artificial obstacle, is, as has been said, the fire of suitable, mobile, light Q.F. artillery and carefully disposed minefields. Inundations are likely to be rendered useless by the tank becoming an amphibious machine.

GENERAL CONCLUSIONS

The tank was the one complete British innovation in the war and a great one. The resurrection of an old weapon, it was forced into a fresh existence during hostilities by the needs of the war, and created for a special purpose. In essence it amounted to the addition of bullet-proof plate and armament to an existing agricultural machine which possessed the quality of cross-country mobility. Its immediate purpose was the destruction of the machine-gun—a weapon which, until the tank appeared, was responsible during the war for the loss of more human life than any other, and upon which the Germans at bay, on the defensive, placed so much reliance. With the machine-gun in this connexion is associated the wire obstacle. The combination of the two was the disease for which the tank proved to be the only cure; but, early as the disease was diagnosed, it had grown to be the scourge of the Allies on the western front, whenever they attempted to press forward as demanded by the strategic situation, long before the cure was applied. The tank was the great life-saver of the infantry. To it many thousands of the soldiers of the Allies, principally French and British, owed their lives—infirmen who but for the tanks would have had to repeat, on a larger scale and possibly abortively, the bloody offensives of 1915, 1916 and the first half of 1917. It took the place of the old stereotyped and expensive artillery preparations, with more certain results, and also reintroduced the surprise factor, which the preliminary bombardment prevented, and which the conditions of trench warfare otherwise rendered impossible without the protection to the infantry afforded by it.

A remarkable feature about the introduction of the British tanks was the fact that they were to a great extent forced on the army by the action of certain enthusiastic individuals, of whom one only was a serving soldier. Some of those, also, who were responsible for the creation of the new weapon, from the beginning formulated the tactics for its employment, which were finally after an inexplicably long period put into practice in the field. This was the case with the British and the French. The British first used tanks in Sept. 1916, and first employed them correctly on a large scale on Nov. 20 1917, 14 months later. The French first used tanks in April 1917, and first employed them correctly, on a large scale, on July 15 1918, also 14 months later. And in each case this happened in spite of the proper method having been put forward, and its adoption urged. The only explanation of this policy is that it was due to inherent conservatism and lack of imagination, incredulity concerning the attributes of the new weapon, failure to understand what they implied, and initially lack of patience.

That the tanks achieved their object was shown by the preparations made by Great Britain, France, the United States, Italy and also Germany for the continuation of the struggle in 1919, and by the fact that their manufacture had begun to take up a large proportion of the munition-producing capacity of three at least of the combatants. In regard to results, it is only necessary to recall one major fact, so far as the British were concerned, *i.e.* that after the era of mechanical warfare, as it has been termed, set in, on Aug. 8 1918, and between that date and the Armistice, 50 British divisions were able to defeat 90 German divisions, a reversal of the proportion usually considered to hold between attackers and defenders. The offensive had at last obtained the superiority, and strength could no longer be estimated by the counting of heads. During the war the German infantry confessed itself impotent against tanks. But since the war not only have the infantry soldiers of other nations come to the same conclusion, but admit that they are often helpless without tanks to assist them. In certain circumstances they demand the assistance of these machines, and they are right. In regard to the influence of the new arm on the result of the war amongst a mass of corroborative evidence, one statement includes and covers all others. On Oct. 2 1918, when the end was fast approaching, the report to the heads of the Reichstag parties made by the representatives of German military headquarters began with the following words¹.—

"The Chief Army Command has been compelled to take a terribly grave decision and declare that, according to human possibilities, there is no longer any prospect of forcing peace on the enemy. Above all two facts have been decisive for this issue. First, the Tanks— . . ."

Such an admission, wrung after four years from those who had confidently started the World War, is sufficient.

In regard to the different ways in which tanks established their military value, apart from the actual results achieved, some instructive statistics have been prepared of their action from the aspect of the "economics" of war.² In fighting man-power a brigade of 144 tanks has a fire-power equivalent to that of 24 light batteries of six guns each, and nearly 200 more machine-guns than are carried in a division. An infantry division accompanied by one battalion of tanks can attack three times the frontage that can be attacked by a division unaccompanied by tanks. The fighting infantry in three divisions is 21,000 men, of one tank battalion 500. The saving in man-power is therefore 23,500, or 63%, and with equivalent fire-power the chances of casualties are reduced. As to economy in infantry casualties, the losses on the first day at the battle of Cambrai (a tank battle) were approximately 1,000 per division engaged; at the battle of the Somme (an artillery battle) there were 3,000. Between July and Nov. 1917, when tanks were used on impossible ground 258,000 casualties were sustained by the British; between July and Nov. 1918, when tanks were used on possible

¹ Report by Col. Bauer, Chief of the Artillery Department.

² The Gold Medal (Military) Prize Essay for 1919 by Brevet-Col. J. F. C. Fuller (*Journal of the Royal United Service Institution*, May 1920). These statistics refer to the experience of the British.

TABLE A.—Particulars of British Tanks

Type of Machine	Date of Commencement of Design.	Date of First Standard Machine.	Weight in Fighting Trim in Tons.	Horse-Power per Ton.	Length Overall.	Width Overall.	Height to Top of Tracks.	Armour Thickness.	At Normal Engine Revolutions Speed in Miles per Hour.					Maximum Width of Trench that can be Crossed without Falling in.	Crew.	Number of 6-pdr. Guns Carried.	Number of Machine-Guns Carried.	Theoretical Tractive Force of Machine in First Speed, in Tons.
									First Gear.	Second Gear.	Third Gear.	Fourth Gear.	Reverse.					
Mark I . . .	Oct. 1915	Dec. 1915	Male, 28 Female, 27	3.75	ft. 32 in 6 with tail, 26 5 without tail	ft. 13 9 in 7 4½	ft. 7 4½ in 6 to 12 mm.		0.75	1.3	2.1	3.7	0.94	10	8	0, female 2, male	5, female 4, male	23.7
Mark II . . .	Feb., 1916	Jan. 1917	Male, 28 Female, 27	3.75	ft. 32 in 6 with tail, 26 5 without tail	ft. 13 9 in 7 4½	ft. 7 4½ in 6 to 12 mm.		0.75	1.3	2.1	3.7	0.94	10	8	0, female 2, male	5, female 4, male	23.7

ground, the Germans lost 284,000 prisoners alone. As to economy in artillery personnel, at the third battle of Ypres 121,000 artillery personnel, were used on a front of 17,000 yd., the maximum penetration attained on July 31 (one day) being 3,300 yards. At Cambrai 4,100 tank personnel carried out the work normally done by the guns on a front of 14,000 yards. The maximum penetration attained in one day was 9,500 yards. As to economy in cavalry personnel, the personnel of all ranks in a cavalry division (without the Royal Horse Artillery) would suffice to man and equip three brigades of Whippet tanks or 540 machines. As to economy in ammunition, at the battle of Arras, on a front of 17,000 yd., 2,007,544 shells, weighing 57,000 tons, were fired; at the third battle of Ypres, on the same frontage, 3,107,363 shells, weighing 93,463 tons, were fired. At Cambrai, on a 13,000 yd front, 293,149 shells, weighing 5,824 tons, were expended. It is shown that the use of tanks also leads to economy in munition manufacturing man-power, in shipping and land transport, in weight carried by the soldier, in labour on the battlefields, in property damaged, in forage or food, in time and in cost of production. In regard to the latter item the cost of projectiles and explosives alone for 1918 was £320,860,344 and for the undeveloped new arm, tanks, £9,587,960. This inevitably leads to speculation as to what results might have been had Mr. de Mole's suggestion made in 1912 been taken up and developed, even at the cost of 12 hours' conduct of the war in 1918.

The principle of mechanical warfare and the advantage of using power-driven machines instead of human and animal muscle having been established in one particular direction, there is little doubt but that it will be applied in others. In future, there will be larger and smaller fighting tanks developed from those born in the World War. They will be speedier, more powerful and have a far longer range of action. Some will also be amphibious, and all will be less easy to stop than the present somewhat embryonic machines. The principle of track propulsion will be applied to vehicles of all types and not confined to fighting machines, and will to a great extent eliminate the necessity of using roads or railway, and place the movement of armies on a "two-dimensional" basis instead of being on a one-dimensional basis as it has in the past. Future fighting tanks will in certain theatres be able to replace cavalry and may against a civilized enemy be able to carry out, with aeroplanes, those long-distance raids against H.Q. and important points far behind the fighting-line, which since the advent of the machine-gun cavalry cannot execute, will give greater facility both for the release of gas in large quantities, if gas is used, and also for obtaining protection against gas. The fighting machines will be very largely used in conjunction with action in the air, and the two services will be complementary and mutually helpful. Large tracts of roadless country which have to be held against an uncivilized enemy, or a hostile population, will provide the first opportunities for the development of this combination, on account of the saving that will be effected in men and animals, the most expensive and delicate parts in an armed force. In killing-power, mobility, and endurance, one efficient mobile machine with its crew and machine-guns will be able to take the place of many infantry or cavalry soldiers and many horses, and will cost less to maintain and feed. In the United States the possibility of the "motorization" of all war transport and of eliminating the horse was in 1921 being fully discussed, and if the signs are read correctly this will be the general tendency, so that the great wars on land of the future will be practically horseless and conducted by far fewer men in the field and more men in the factory and workshop than has been the case in the past. Strength for war will not in the future be estimated by counting heads, for, beyond the minimum necessary, the greater the number of human beings in a force in the field the greater will be its vulnerability. The introduction of the tank in 1916 upset all the existing values of field defences, and its natural and inevitable evolution will cause a revolution in the methods of war as great as that in tactics caused by its original appearance.

H. Tennyson d'Eyncourt, K.C.B., D.S.O., are reproduced on a reduced scale by permission of the publishers of *Engineering*. (E. D. S.)

TANNENBERG, a village of East Prussia, 20 m. S.W. of Hohenstein. It has given its name to two battles of great importance in German history, the battle of July 15 1410, in which the Poles and Lithuanians destroyed the forces of the Teutonic Order (see 21.005), and that of Aug 26-31 1914, in which the German VIII Army under General-Oberst von Hindenburg destroyed the Russian II Army commanded by General Samsonov. The latter is described in detail under the heading MASURIA, BATTLES IN. For a critical account of the former, the story of which has been overlaid by a mass of legends, see Delbruck, *Gesch der Kriegskunst*, vol. iii, book iv., ch. 6.

TARKINGTON, [NEWTON] BOOTH (1869-), American writer, was born in Indianapolis, Ind., July 29 1869. After studying at Phillips Academy, Exeter, Mass., he entered Purdue University, Lafayette, Ind., but two years later transferred to Princeton, where he graduated in 1893. At first he intended to follow a business career, but after a few years devoted his time to writing. He was elected to the Indiana House of Representatives for the term 1902-3. In 1918 he received the degree of Litt D from Princeton. In 1920 he was elected to the American Academy of Arts and Letters. The same year he was engaged as a writer of photo-plays by the Goldwyn Pictures Corporation. His first story, *The Gentleman from Indiana*, was published in 1899, having appeared already as a serial in *McClure's Magazine*. In 1900 his reputation was established by *Monsieur Beaucaire*, which he successfully dramatized (with E. G. Sutherland) in 1901. In 1919 he was awarded the Pulitzer Prize by Columbia University for his novel, *The Magnificent Ambersons* (1918).

His other stories include *The Two Vanrevels* (1902), *Cherry* (1903), *The Conquest of Canaan* (1905), *Guest of Quenay* (1908), *Beauty and the Jacobin: an Interlude of the French Revolution* (1912), *Penrod* (1914), *Penrod and Sam* (1916), *Ramsey Mulholland* (1919), *Alice Adams* (1921). His plays include *Cameo Kirby* (1907), *Your Humble Servant* (1908), *Master Antonio* (1916), *The Country Cousin* (1917, with Julian Street), *The Gibson Upright and Up From Nowhere* (1919, both with Harry Leon Wilson), *Clarence* (1919).

TATA, SIR RATAN (1871-1918), Parsee financier and philanthropist, was born at Bombay Jan. 20 1871, the son of the famous Parsee merchant Jamsetji Nasarwanji Tata (see 26.448). He was educated at St. Xavier's College, Bombay, and afterwards entered his father's firm. On the death of the elder Tata in 1904, Ratan Tata and his brother Dorabji Jamsetji Tata (b. 1859) inherited a very large fortune, much of which they devoted to philanthropic works of a practical nature and to the establishment of various industrial enterprises for developing the resources of India. An Indian institute of scientific and medical research was founded at Mysore in 1905, and in 1912 the Tata Iron and Steel Co. began work at Sachi, in the Central Provinces, with marked success. The most important of the Tata enterprises, however, was the storing of the water-power of the Western Ghats (1915), which provided the city of Bombay with an enormous amount of electrical power, and hence vastly increased the productive capacity of the Bombay industries. Sir Ratan Tata, who was knighted in 1916, did not confine his benefactions to India. In England, where he had a permanent residence at York House, Twickenham, he founded (1912) the Ratan Tata department of social science and administration at the London School of Economics, and in 1912 established a Ratan Tata fund at the university of London for studying the conditions of the poorer classes. He died at St. Ives, Cornwall, Sept. 5 1918.

TAUSSIG, FRANK WILLIAM (1859-), American economist (see 26.456), was during 1917-9 chairman of the U.S. Tariff Commission, which made a special study of commercial

treaties and prepared much material for the American Peace Commission in Paris. In March 1919 he was called to Paris to advise in the adjustment of commercial treaties, and in Nov. on invitation of President Wilson, attended the second industrial conference in Washington for promoting peace between capital and labour. He was a strong supporter of the Covenant of the League of Nations. He was the author of *Principles of Economics* (1911, 2nd ed. 1915), *Some Phases of the Tariff Question* (1915); *Investors and Money-Makers* (1915); and *Free Trade, the Tariff, and Reciprocity* (1919).

TEISSERENC DE BORT, LÉON PHILIPPE (1855-1913), French meteorologist, was born in Paris Nov. 5 1855, the son of an engineer. He began his scientific career in 1880, when he entered the meteorological department of the Bureau Central Météorologique in Paris under E. E. W. Mascart. In 1883, 1885 and 1887 he made journeys to N. Africa to study geology and terrestrial magnetism, and during this period published some important charts of the distribution of pressure at a height of 4,000 metres. In 1892 he became chief meteorologist to the Bureau, but resigned in 1896 and founded a private meteorological observatory at Trappes, near Versailles, where he carried out investigations on clouds and the problems of the upper air. In 1898 he published an important paper in *Comptes Rendus* detailing his researches by means of balloons into the constitution of the atmosphere. His discovery of the so-called isothermal layer, or stratosphere as it is now generally called, will always stand out as one of the most important events in the study of the upper atmosphere. He also carried out investigations in Sweden and over the Zuider Zee, the Mediterranean and the tropical region of the Atlantic, and fitted out a special vessel in order to study the currents above the trade-winds. He was elected a fellow of the Royal Meteorological Society in 1903, hon. member in 1909, and was awarded the Symons gold medal of the society in 1908. He collaborated with Hugo Hildebrandsson in *Les bases de la météorologie dynamique* (1907). He died at Cannes Jan. 2 1913.

TELEGRAPH (see 26 510*)—Apart from the advances in Wireless Telegraphy (see WIRELESS) and Cable Telegraphy (see SUBMARINE CABLE TELEGRAPHY), progress since 1910 has been seen in various technical directions. The developments in the United Kingdom and in the United States in some respects have differed, and this article therefore considers them in two sections which differentiate not only certain technical and commercial aspects of the subject but also certain distinctive points of view.

UNITED KINGDOM

One of the most important developments in type-printing telegraphy is the adaptation of the Baudot for duplex working by A. C. Booth in 1905. This forms the basis of all modern multiplex systems, and has led to a great increase in the output and flexibility of such systems with a consequent considerable extension of their use.

FIG. 1.

Booth-Baudot.—The underlying principle of the Booth-Baudot will be understood by reference to fig. 1. It will be seen that the outgoing signals from the sending rings of the distributor at the home station divide differentially as the line relay and therefore do not affect the receiving apparatus which is connected in the local circuit via the receiving rings of the distributor. Installations of

double, triple, quadruple, quintuple, and sextuple duplex have given excellent results in the British Post Office service during a number of years. The method of driving the mechanism of the Baudot distributors and receivers has been changed from weight driven gear, to electric motor drive. In the case of the receivers, a small series motor with belt drive is used, while the distributors are driven by the La Cour phonic motor. In both cases a considerable saving is obtained in first cost and maintenance expenses with the advantages of more satisfactory working and greater facility in changing apparatus when necessary.

The Carpentier method of automatic transmission on Baudot circuits has recently been reintroduced in the British Post Office, but with several important improvements.

In offices where a large number of keyboard perforators are used, each having its own particular lay-out, the change from one instrument to another caused serious difficulty from an operating standpoint. This difficulty was much felt with the original Carpentier keyboard, in which, owing to the exigencies of the Baudot code, the keys for the numerals were spread over the keyboard instead of being arranged on the first row of letter keys as in most typewriters. Carpentier sought to minimize this difficulty by adding an extra row of keys for the numerals, and a similar arrangement was adopted in the Morse keyboard perforators such as the Gell and the Kleinschmidt.

Messrs. A. C. Booth and A. S. Willmott have now invented a device which enables the keyboard for any type of machine telegraph, whatever the code used, to be arranged exactly as in a typewriter, thus allowing the numerals to be placed in their standard positions without the extra row of keys.

The Booth-Willmott-Baudot keyboard perforator punches the 5-unit code transversely on a paper tape which is of the same size as that used in the Murray and Western Electric instrument (see hereafter), enabling the transmitters of either of these installations to be used in conjunction with it. Switches are provided on the instrument tables so that any particular arm of the multiplex may be worked automatically from a transmitter fed by a Booth-Willmott perforator or by direct-sending from an ordinary Baudot keyboard sender at will.

Murray Multiplex.—The difficulty experienced by Baudot operators in manipulating accurately the direct-sending keyboards

FIG. 2.

in time with the cadence signal at speeds much in excess of 30 words per minute led Murray to adopt the Carpentier method of automatic transmission in his multiplex system. The main features of the Booth-Baudot system are utilized, but the operators perform on perforators which have keyboards similar to that of an ordinary typewriter and do not have to keep in time with a cadence signal. Each key of the perforator, when depressed, perforates in a paper tape, a particular combination of holes in accordance with the arrangement of the five-unit code adopted by Murray. The tape thus prepared has its perforations across the slip and not longitudinally as in the case of the Murray automatic system, the use of which has been abandoned, so that a great saving in the cost of paper results.

Fig. 2 shows a portion of the Murray multiplex transmitting tape perforated to represent the word "telegraph". From the perforator, the tape passes directly into an automatic transmitter, which has five selecting needles, each controlling a contact lever resting

* These figures indicate the volume and page number of the previous article.

normally against a bus-bar connected to the spacing pole of the line battery. When a needle passes into a hole in the tape the corresponding contact lever moves over and makes contact with a bus-bar connected to the marking pole of the line battery. The positions of the contact levers are therefore determined by the perforations in the tape and as each lever is connected to its own particular segment on the sending ring of the distributor, the signals representing a character are sent out to line, one after the other, as the brushes pass over the segments. Immediately the brushes have passed over the last of the segments allocated to a particular transmitter a current impulse is sent from another ring of the distributor through a "cadence" electromagnet in the transmitter, which when operated withdraws the selecting needles that have entered perforations and propels the tape forward sufficiently to bring the next group of perforations into position above the selecting needles. Provision is made for preventing mutilation of the paper tape when the transmitter overtakes the perforator, by arranging for the tightening of the tape to actuate a lever situated between the two instruments. When the lever is pulled down the armature of the cadence electromagnet is prevented from moving. As soon as the tape slackens the lever rises and transmission is continued. For the reception of signals Page printers are employed somewhat similar to those which were used in the Murray automatic system, but differing from them in that the five selecting combs, which determine the letter to be printed, are positioned by electromagnets instead of by a perforated tape. The normal speed of working of each arm of the Murray multiplex is 40 words per minute, although speeds in excess of this may be attained.

REFERENCES.—D. Murray, *Practical Aspects of Printing Telegraphy*, I.E.E. Paper (1911), latest edition of *Herberts Telegraphy*, *Post Office Technical Pamphlet for Workmen*, B7.

The Western Electric Multiplex—This system is also based on the Booth-Baudot duplex and came into use in 1914. The adoption of a method of correction from the actual working signals themselves, instead of utilizing special correcting signals as in the Baudot and Murray systems, results in a saving of line time and therefore gives a greater output on difficult lines.

The transmitters and perforators are the modern developments of Carpentier's but the printer used types the message in page form instead of on a paper tape as in the Baudot system, from a type wheel which rotates from character to character as may be required. This printer has not given entirely satisfactory results, and is being superseded by one in which type bars are used in place of a type drum and the paper is kept central instead of being moved sidewise to and fro. The phonic wheel distributors are driven by electrically vibrated tuning-forks, which possess an advantage over vibrating-reeds in that they may be placed on the instrument table instead of being fixed to a steady support as is required in the case of reeds.

The Kleinschmidt Electric Co. of New York have recently designed a very compact column printer which may be used on Western Electric multiplex circuits. As in the Murray printer, there are five selecting combs which are operated by electromagnets. When the combs have been positioned, during the reception of a character, certain slots in the combs are thereby brought into alignment allowing a pull-bar attached to one extremity of the required type-bar lever to fall into them. Directly after the combs have been moved and the type-bar lever selected, a contact is closed mechanically, completing a circuit through a printing magnet which, when it operates, causes the selected pull-bar to be impelled forward, thus projecting the free end of the corresponding type-bar lever against an ink ribbon and printing the required character as in a typewriter.

Roberts, "A New Type Printing Telegraph System," *I.P.O.-E.E. Journal* (vol. viii, p. 193); *Post Office Technical Pamphlet for Workmen*, B7.

The Siemens Automatic System—The original Siemens automatic system used an 11-unit code actuating a receiver which printed the incoming signals in Roman characters on photographic paper. The preparations required for the received slips, which had to be developed chemically, impaired its usefulness for actual traffic, and the system was superseded in 1912 by one using a 5-unit code and a revolving type-wheel. The latter is now extensively used in Germany and to a limited extent in other countries.

As in the case of the Creed and other automatic systems there are several perforating operators and one transmitting operator at the sending station. The paper tape from the keyboard perforators is passed through the selecting needles over the selecting needles, con-

trolling their upward movement and determining the polarity of the current impulses sent to line during each revolution of a brush over the five segments of a distributor. The sending distributor brush arm is driven by a shunt wound motor whose speed is kept steady by means of a heavy flywheel mounted on the spindle. Unison with the brush arm of the receiving distributor at the distant station is maintained by the actual working signals. The receiving and translating arrangements of the receiver are almost entirely electrical, and printing is effected by the discharge of a condenser through an electromagnet, the armature of which presses momentarily a paper tape against a revolving type-wheel. This tape is afterwards pasted on ordinary message forms as in the Baudot system. In addition to the printing tape, the incoming signals can also actuate a keyboard perforator to provide a perforated tape for retransmission purposes. The system may be worked either simplex or duplex and is capable of giving a maximum speed of 166 words per minute in each direction.

The Morkrum Teletype—This is a single-line system of printing telegraphy which has been recently developed by the Morkrum Co. of Chicago, U.S.A. It may be duplexed, and is suitable for short lines over which the traffic is not very heavy.

The apparatus comprises two units, a keyboard transmitter, and a printer, which are mounted on one base to form a very compact combined sending and receiving instrument. The keyboard is arranged as for a standard typewriter, and is a direct-sending instrument the keys of which when operated allow a cam-shaft to revolve opening and closing the line circuit according to the 5-unit code. Starting and stopping impulses are sent over the line to start and stop the selecting mechanism of the printer so that from transmission point of view the system has actually a 7-unit code. A feature of the system is the controlling and selecting mechanism of the printer, which is an ingenious combination of the Hughes and Baudot printers. The received message is printed on tape in exactly the same way as in the Baudot printer and afterwards gummed on ordinary message forms.

The maximum speed of operation of the keyboard is limited to 45 words per minute and a device is provided which is actuated when this speed is exceeded and prevents the keys being depressed too rapidly.

The Creed System—One of the principal drawbacks to the original Creed system was the use of compressed air for working the apparatus, which in a large number of offices necessitated the installation of a special pneumatic plant. Moreover, the pneumatic Creed printer had a maximum speed of only 120 words per minute, so that on lines where the working speed was much in excess of this figure it was necessary to install two printers in order to deal expeditiously with the traffic. The latest Creed instruments, however, have been designed to work electrically, they are much simpler in their construction and give speeds up to 200 words per minute.

For the preparation of the transmitting tapes, Gell and Kleinschmidt perforators are generally used, each of which has a keyboard similar to that of an ordinary typewriter. The depression of a key selects, through a system of levers, the punches required to perforate the holes in the tape for the corresponding signal, and closes a circuit through an electromagnet, the armature of which forces the selected punches through the paper tape. As these perforators prepare Wheatstone slip their mechanism is necessarily much more complicated than that of keyboard perforators designed for a 5-unit code, in which all letters are of the same length, because in the former a differential feed varying from two-tenths of an inch to over one inch is required owing to the varying length of the letters. These machines will work as fast as a typewriter, but 80 words per minute is regarded as the limit for practical purposes.

Gulstad Relay—In 1898 Gulstad of Copenhagen invented a modified form of polarized relay, known as a vibrating relay, the use of which has enabled much greater speeds of working to be attained on underground and submarine circuits, and in some cases allowed repeaters to be dispensed with. In general construction it is similar to the British Post Office standard relay, but, in addition to the usual line coils, has two extra windings on the same cores. These windings are connected to a local battery

in such a manner that the relay tongue is caused to vibrate between the contact points, when the current through the line coils is insufficient to maintain it on either of the contacts.

The principle of the relay may be understood by referring to fig. 3. It will be seen that the ends of the local windings are joined to terminals B and C and their centre to terminal A, which is joined through an adjustable resistance Y to the relay tongue. This resistance is for regulating the local current and keeping it below the value of the steady current through the line coils. Terminal B is connected to earth through a condenser K, while C has a resistance coil X in its earth lead.

Assuming that there is no current in the line coils and that the relay tongue has just reached the marking contact, there will then be a momentary rush of current through the winding AB to charge the condenser K, in a direction to keep the tongue to the marking side, thus preventing any tendency of the tongue to rebound. This charging current dies away rapidly, however, and directly its strength falls below the steady current flowing through the winding AC, the preponderance of the latter causes the tongue to move toward the spacing contact. Immediately the tongue leaves the marking contact, the condenser K discharges through both windings BA and AC in such a direction as to accelerate the movement of the tongue, so that its transit time from one contact to the other is thereby lessened.

When the tongue reaches the opposite contact the condenser K is again charged, but this time from the other pole of the battery, a similar cycle of effects therefore takes place on that side and the

FIG. 3.

tongue moves in the reverse direction. In this manner the relay tongue is kept vibrating, at a speed depending on the values given to the condenser and resistance. In practice the adjustments are such that the rate of vibration of the tongue under the control of the local current is approximately equal to the rate at which the transmitter at the distant station sends reversals at working speed. When this obtains, the signals passing through the line coils merely determine the length of time that the tongue remains in contact with either stop, its movement therefrom being effected by the local current through the local windings as soon as the strength of the line current falls below that of the local current in the coil AC. It is this effect combined with the action of the condenser in lessening the time of transit of the tongue, that enables a higher speed of working to be attained on long and difficult circuits than if ordinary polarized relays were used.

In the original Gulstad relay the line coils were not differentially wound; it could be used, therefore, only on bridge duplex or simplex circuits. To utilize the advantages of the Gulstad principle on differential duplex circuits, the British Post Office has modified the Post Office standard relay, by adding extra windings and terminals. This modified instrument is known as a "G" relay and is equally suitable for differential or bridge duplex working. The internal and external connexions of this relay are shown in fig. 4, in which the dotted lines indicate the extra coils. For the correct reception of the incoming signals a Wheatstone receiver is connected to the relay tongue.

Tele-photographic Systems—In 1909 T. Thorne Baker read a paper before the Royal Institution in London describing his "telegraph" process of transmitting pictures over long distances. The method, which was used on a large scale by the *Daily Mirror* between London and Paris, is based upon the Bakewell copying telegraph.

FIG. 4.

Synchronously rotating metallic drums, driven by electric motors, are employed one at each end of the telegraph line over which it is desired to transmit, say, a picture. A half-tone photograph of the picture is first printed upon thin sheet lead and subjected to a process which breaks up the photograph into a number of dotted lines printed in fish glue. This record is fixed round the transmitting drum, which is traversed spirally by an iridium stylus. The contact of the latter with the lead is interrupted every time one of the fish glue dotted lines comes beneath it, for duration depending upon the width of the line. The lead sheet is connected to the line, so that the transmitting instrument sends a series of electric currents whose periods of duration are determined by the width of the lines composing the photograph. At the receiving station, the rotating drum carries a piece of absorbent paper impregnated with a colourless solution, which turns black or brown when decomposed by an electric current. Every brief current through the paper causes a mark to appear, having a width depending on the duration of the current. The arriving currents are therefore arranged to pass through a platinum stylus under which the receiving drum rotates, then through the moistened paper resulting in the production of a number of marks on the paper due to chemical decomposition. These marks gradually combine to produce the picture at the transmitting station.

Foss and Petersen Method.—In this system a high frequency generator capable of producing sparks is used at the receiving station. The sparks so produced are capable of puncturing a paper wrapped round a metal drum which rotates in unison with a similar drum at the sending station.

The line wire is arranged so that when the sending end is connected to earth the generator is partly short-circuited, thus suppressing the sparking. At the sending end the shunting of the generator is effected by means of a contact pin passing over a cylinder on which the writing or illustrations are inscribed in insulating ink so that the shunt circuit is cut out each time the pin passes part of the writing (see Patent Specification No. 105,914, 1917). (W. No.)

UNITED STATES

Technical developments made after 1910 practically revolutionized telegraphy as practised in the United States. These include printing-telegraph arrangements applied to telephone as well as to telegraph circuits, simultaneous telephone and telegraph operation for long small-gauge cable circuits, and the use of alternating currents with resonant circuits in the so-called carrier systems for multiplexing wire conductors.

Radical changes were also made in the arrangements for and the methods of handling telegrams in large offices. Belt conveyers, typewriters, pneumatic tubes, automatic time-stamps and other labour-saving devices came to be used to a large extent. About 75% of all telegrams handled by the Western Union Telegraph Co. over trunk circuits in 1921 were transmitted and

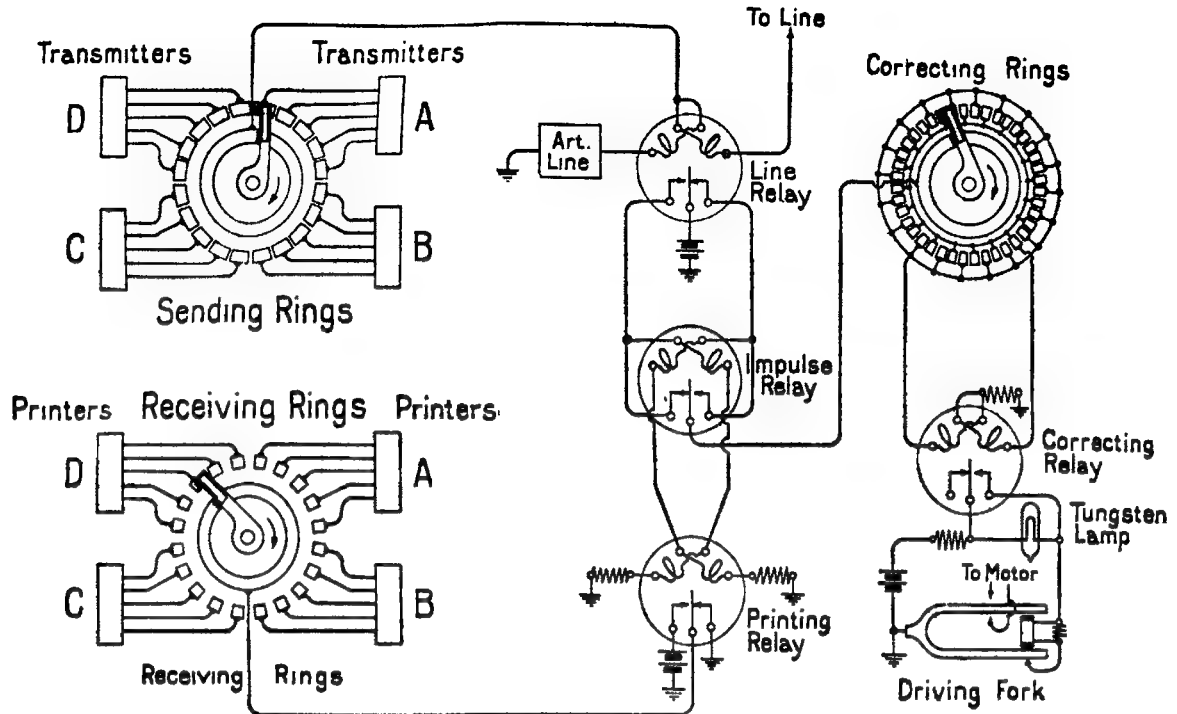

FIG. 5.—Simplified Terminal Circuit of Multiplex Printer System.

received by printing-telegraph apparatus. The introduction of machine telegraphy took place after 1910.

Progress can be divided into two general classes: (1) that relating to terminal equipment, such as printers; and (2) that relating to the methods of working lines.

Printing Telegraphy

(a) **Multiplex System**—The multiplex system giving double-duplex, triple-duplex and quadruple-duplex service, as applied in America, was that developed jointly by the Western Electric Co and the Western Union Telegraph Co. It uses the Baudot code and a system of speed correction for rotating distributors in which correcting impulses are generated from the character signals, thus saving line time.

The fundamental features of one arrangement for quadruple-duplex operation are shown in fig. 5. The sending, receiving and correcting rings are parts of a distributor driven by a La Cour or phonic-wheel motor. The common sending ring is connected to the midpoint of a differentially wound line relay and the common receiving ring to the armature of a printing relay included in the local circuit of the line relay. This local circuit also includes an

impulse relay, so arranged that short-current impulses are sent to the common ring of the set of correcting rings when the line relay armature moves from one contact to the other. These impulses come at intervals determined by the signals transmitted by the distant station. There are twice as many correcting segments as sending segments, and these are alternately connected to the windings of a correcting relay. One distributor on a circuit sets the speed for the other and if the corrected distributor is running too fast, the operation of the correcting relay causes the driving fork for its motor to be retarded in its rate of vibration. If, on the other hand, the distributor is running too slowly, the fork is accelerated. It is essential to secure correcting impulses when all printing channels are idle. This is done by reversing the polarity of the marking signals of one or more channels. Various types of printer units have been successfully used with this system. Speeds as high as 50 to 60 six-character words per minute per channel are maintained by operators. The multiplex printer system has thus greatly increased operators' loads as well as the number of telegraph channels which can be obtained from each line circuit. Means have been developed for economically extending the single channels of a multiplex-printer system from the multiplex terminal station to branch offices.

(b) **Start-Stop Printer Systems**—Successful systems giving single-channel working, or two-channel working when operated duplex,

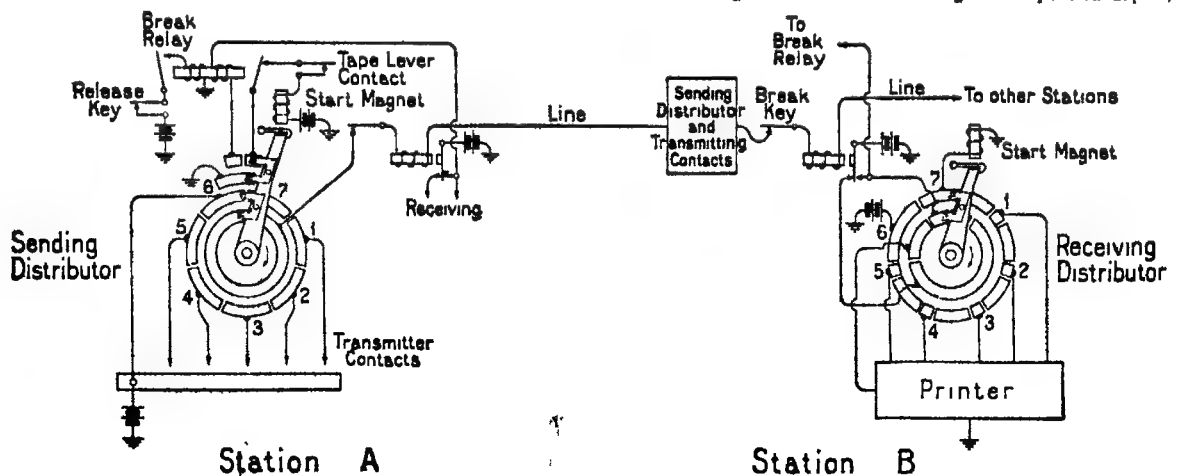

FIG. 6.—Circuit of Start-Stop Printer System.

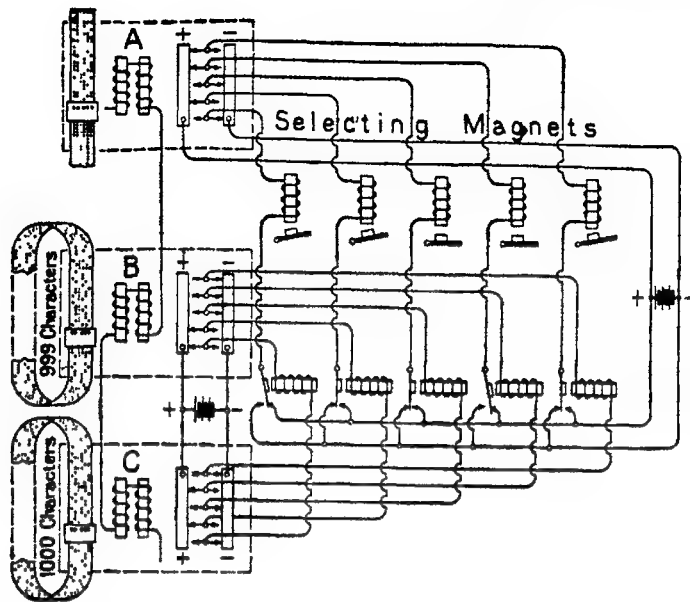

FIG. 7.—Selecting Circuit of Cipher System

have been developed for inter-communicating purposes among a group of stations. These systems have been used to a considerable extent with telegraph circuits obtained from telephone circuits.

One of these systems employing motor-driven distributors at each station is shown in fig. 6. The sending distributor at one station and the receiving distributor at the other are indicated in detail. The distributor brush arms driven through a friction clutch are normally held stationary by a latch and make one rotation for each character transmitted or received. A start impulse, usually the opening of the line circuit for a brief interval, releases the receiving start latches so that all receiving distributors start rotating. The five impulses of the Baudot code which follow the start impulse are distributed properly to the selecting magnets or elements of a printer by the receiving distributors if their speeds coincide approximately with that of the sending distributor. Close synchronism is not required since all distributors are stopped and caused to start from the same initial position for each character.

FIG. 8.—Terminal Arrangement for Metallic Telegraph Cable Circuit.

An important feature is the method by which any receiving station can interrupt the sending station and obtain control of the circuit. As shown, this is accomplished if the line circuit is interrupted by the break key during the time the sending brush is passing over the sixth segment when a break relay at the sending station will be energized to open the circuit of the magnet controlling the latch. The release key will then have to be operated to permit further sending. This printing system has been used to a considerable extent for news distribution, where in many cases a number of sending and receiving stations are connected to one circuit and means must be provided to allow any station to obtain control of the circuit. Keyboard arrangements which may be used for perforating tape or for sending directly to the line have been developed and found very satisfactory for this kind of service. The Western Electric type-bar printer has been found very satisfactory for news service. This is provided with a stationary paper platen and a moving type-bar basket. Books containing carbon paper for making a large number

of copies and forms holding wax stencil sheets may be readily inserted into the machine. Means are provided for adjusting the strength of the blow of the type bars so that one to twenty copies can be secured.

(c) *Cipher Printing System.*—A printing system for rapidly ciphering and deciphering telegraph messages has been developed. It is thought that cipher messages prepared by this system are absolutely unbreakable. It was successfully applied by the U.S. Army Signal Corps during the war and tests made indicate that messages can be ciphered and deciphered by this means with greater accuracy and many times faster than by other methods.

This system was developed by the engineers of the American Telephone and Telegraph Company. Its principles are illustrated in fig. 7. A message prepared in perforated tape form by the ordinary printer perforator passes through transmitter A. This would ordinarily control the selecting magnets of a printer or an automatic perforator. Key tapes B and C, however, passing through ordinary tape transmitters, control relays which interfere with the normal operation of the selecting magnets so that the resultant selection for any character of the message may be any one of the characters of the Baudot code. The characters of the key tapes are selected at random and B is one unit less in length than C. All tapes are stepped in unison. Repetition in the resultant key will not occur until B has revolved 1,000 times. The proper starting position of the key tapes B and C for any message may be indicated by six characters which may be

FIG. 9.—Polar Relay for Cable Telegraph System.

ciphered by an additional key. In deciphering the cipher message tape is placed in transmitter A and the characters combined with the proper key to obtain the original message

Methods of Working Lines

(a) *Simultaneous Telephone and Telegraph Working*—Considerable advance has been made in the technical knowledge of simultaneous telephone and telegraph operation of line circuits. Hand telegraph systems and single-channel printer systems usually operate at dot speeds of 10 to 25 per second and it has been found that in order to secure satisfactory service it is necessary to design line systems to transmit a frequency band of about 100 cycles per second. Since telephone frequencies range from about 250 to about 2,500 cycles per second, it is possible to secure satisfactory telegraph operation from telephone circuits by using frequencies below the lowest telephone frequencies and frequencies above highest telephone frequencies. More than 600,000 m. of telegraph circuits are obtained from telephone circuits in the United States.

FIG. 10.—Diagram of Polar Relay for Cable Telegraph System

(b) *Metallic Telegraph System*—The increase in knowledge of the fundamental requirements of simultaneous telephone and telegraph operation has enabled a telegraph system to be developed for operation over long small-gauge telephone cable circuits. This system is arranged for metallic circuit working using a relay operating with a current of approximately 2 milliamperes. The general circuit arrangements of this system are shown in fig. 8. The cable circuit is divided by a composite set or filter into two branches, one for the telephone and the other for the telegraph, the telegraph branch absorbing frequencies below the telephone interval. All metallic lines in a single office are supplied from a common battery. The type of polar relay selected for this circuit is shown in fig. 9 and the magnetic principle illustrated in fig. 10. The relay is provided with a Gulstad vibrating circuit and the armature, a reed, is the cross piece of a magnetic bridge. The line windings surround the armature, and a current in one direction causes the armature to move toward one pole while a current in the opposite direction causes it to reverse its motion. Chatter at the contacts is practically prevented by cushioning contact springs attached to the armature. This system has been designed for cables containing as many as 300 working circuits. A telegraph repeater is shown in fig. 11. The simultaneous operation of telephone and telegraph circuits has been carefully worked out in connexion with the design of long interurban cables and the equipment used in connexion with them.

(c) *Carrier Current Multiplex System*—One of the most interesting telegraph developments is the so-called Carrier Current System in which multiplex operation is secured by the use of a number of alternating currents of different frequencies and of resonant circuits for selecting them at the line terminals. This system uses vacuum tubes for generating, amplifying and rectifying the alternating cur-

rents and represents a radical departure in telegraphy. The circuits are of high signal quality, very stable in operation and free from the duplex balance difficulties of direct current systems. This system has enabled the following communication facilities to be obtained commercially from a single pair of open wires. Twenty 1-way carrier channels, four 1-way direct current channels, and one and one-half telephone circuits including the phantom. The carrier telegraph circuit is illustrated in fig. 12. The terminal apparatus for one 2-way channel, which repeats between the carrier circuit and the direct current extension circuit, is mounted upon a vertical panel similar in appearance to that of the metallic telegraph system. The same sensitive relays are used in both systems.

(d) *Rotary Repeaters*—Success has been obtained with the use of rotary repeaters in connexion with telegraph circuits operated by the multiplex printer system. This type of repeater restores distorted line signals to their original form and has enabled printer circuits 3,000 m. in length to be operated successfully at high speeds.

(e) *Fundamental Telegraph-Transmission Research*—Considerable attention has been given to the telegraph-transmission problem and improvements have been made in the methods and means for measuring distortion of telegraph signals. The fundamental transmission requirements for different classes of service have been more carefully enumerated and advances made in the design of artificial lines.

(f) *Interference*—Advances have been made in minimizing interfering currents in telegraph circuits both from high-tension power lines and from neighbouring telegraph circuits. Means have been devised to overcome the effect of differences in ground potentials on grounded telegraph circuits. This arrangement introduces a counter-electromotive force which is automatically adjusted to neutralize the earth-potential difference between any two given points.

(g) *Codes and Sending Machines*—Codes, abbreviations, typewriters and automatic sending machines are now widely used by operators to increase the capacity of manually-operated telegraph circuits. The automatic machine is merely a vibrating reed mounted in a convenient and portable manner, adjusted to vibrate at telegraph speeds and provided with contacts for controlling the telegraph circuit. A movement of the controlling lever in one direction causes the instrument to transmit a succession of dots, the number depending on the length of time the lever is thus held. A contrary movement sends a dash. This instrument permits higher speeds than are otherwise possible to be maintained with considerably less fatigue on the part of the operator. It may be readily connected with any ordinary telegraph circuit.

Codes and abbreviations for shortening messages are used especially in distributing news. The Phillips Code is one that has been generally adopted and an illustration of its use follows:—

Transmitted message:—
t p o t u s w i a d s c g s t s p q p i p q s a.

FIG. 11—Telegraph Repeater for Cable System.

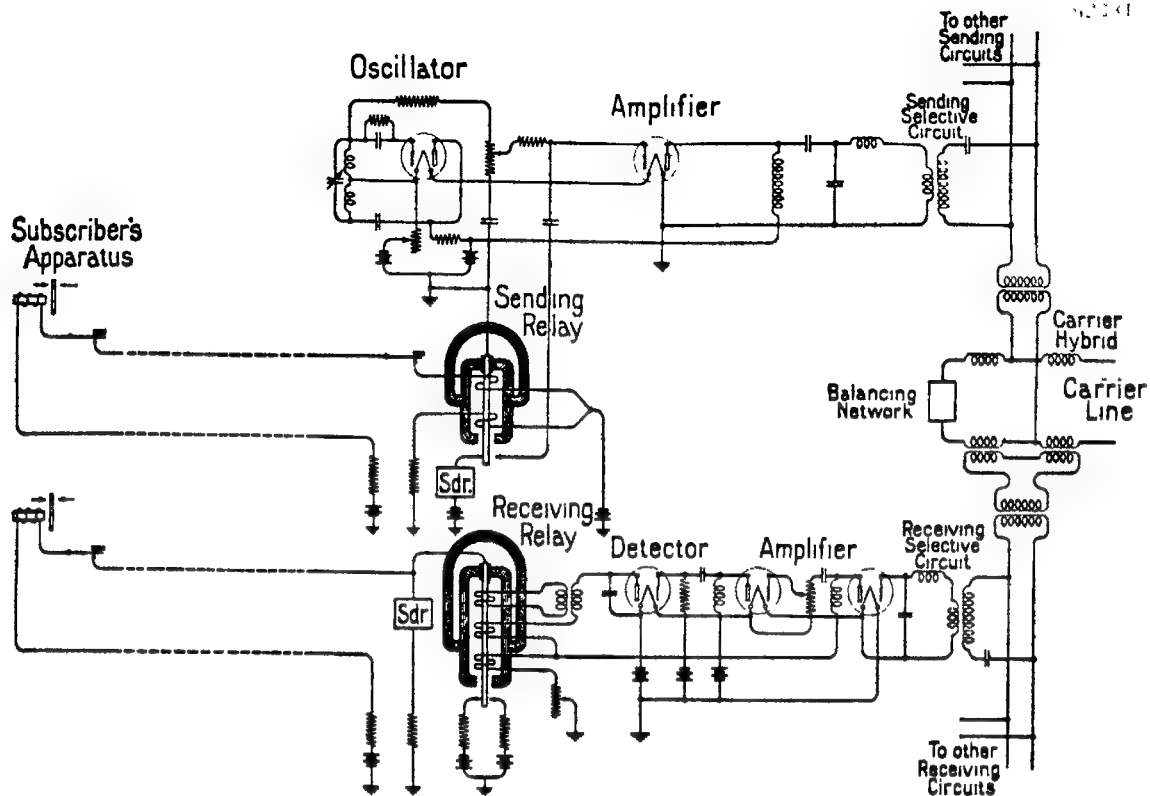

FIG. 12.—Terminal Circuit for Carrier Telegraph Channel.

This would be written by the receiving operator as follows:—

The President of the United States will address Congress this afternoon on the Philippine Question.

Many other schemes are used to save time and cost.

MILES OF TELEGRAPH WIRE OF THE WORLD—JANUARY 1 1910, 1914 AND 1920

(Some of the figures—for the most part those for small places not shown separately—are necessarily in part estimated.)

	SINGLE WIRE		
	Jan. 1 1910	Jan. 1 1914	Jan. 1 1920
Great Britain	311,942	313,166	318,759
Denmark	8,048	8,191	8,500
France	379,888	381,000	715,468
Germany	388,412	459,811	486,714
Italy	126,505	129,500	208,210
Norway	13,120	13,211	16,195
Sweden	40,171	42,194	53,300
Switzerland	16,336	16,476	19,085
Other countries in Europe	826,730	929,072	930,000
Total Europe	2,111,152	2,292,621	2,756,231
Japan	97,300	106,946	127,000
Other countries in Asia	399,030	436,763	553,000
Total Asia	496,330	543,709	680,000
Union of South Africa	46,853	54,201	49,432
Other countries in Africa	110,000	122,159	140,000
Total Africa	156,853	176,360	189,432
United States	1,480,000	1,615,000	1,700,000
Canada	153,000	193,277	214,629
Other countries in North America	78,000	86,805	95,000
Total North America	1,711,000	1,895,082	2,009,629
Total South America	143,590	251,990	333,632
Australia	92,909	108,031	147,276
New Zealand	20,188	25,892	29,700
Other countries in Oceania	14,700	19,319	24,100
Total Oceania	127,797	154,142	201,076
Total throughout world	4,746,722	5,313,904	6,170,000

NOTE:—In the case of countries the boundaries of which have undergone change, the figures for each year represent the number of miles of telegraph wire within the boundaries of that year.

Telegraph wire used exclusively for railroad operation and not open to public use has been excluded wherever possible.

TELEPHONE (see 26.547).—Various improvements were made during 1910-21 in the mechanism and working of the telephone, apart from the introduction of wireless telephony, which is dealt with in the separate article under WIRELESS. Since operating practice and the application of recent inventions are not always the same in the United States as in Great Britain, some developments which are not common to both countries are described in the section headed *United States*. At the end of that section will be found a table showing the expansion of telephone facilities during the years 1910-21 in all countries.

GREAT BRITAIN

Private Branch Exchanges.—The increasing use of the telephone as between one party and another was early followed by a demand for the means of connecting different members of a firm in the same building without the necessity for providing each with a separate line to the public exchange. A further development required that incoming calls for a large firm should be dealt with at a central point in the initial stage so that after ascertaining the business of the caller he could be placed in communication with the particular department concerned. To meet these needs switchboards similar in general principles to those provided for main exchanges have come into use. The call from a local extension or from the main exchange is answered by the branch exchange operator, and the connexion is completed by the medium of connecting cords, or, on small systems, by circuits with which each line is associated by means of a key. In the latter case the depression of any pair of keys on a common connecting circuit places the two corresponding lines into connexion with one another. On the smaller installations where it is probable that an operator is not always available to give prompt attention to calling and clearing signals, the extension stations signal the completion of their conversation direct to the main exchange and simultaneously to the branch exchange. This enables the main exchange to disconnect the circuit promptly, releasing the main exchange circuit and any junction circuits which may have been occupied by the connexion. The prompt release of these circuits is of extreme importance in the economical working of the whole system. On larger branch exchange systems where an operator is in continuous attendance, the main exchange clearing signals are controlled by the withdrawal of the cord connexion at the branch exchange. The advantage to be gained under this scheme lies in the fact that the extension station can call in the branch exchange operator during a conversation and get an established call from the main exchange transferred to another extension station when required. When a branch exchange is used in conjunction with a common battery or automatic switching system, the current for speaking purposes is fed over the main exchange lines on exchange to extension station connexions, and by means of a power lead from the main exchange in the case of extension to extension connexions.

When associated with automatic switching systems the branch exchange operator is provided with a calling dial, so that on each exchange connexion she can dial the number required by any extension station.

Trunk Line Working.—Trunk or long distance working is complicated by the necessity for recording the particulars of all calls, and because instantaneous connexion cannot always be effected owing to the prohibitive cost of providing lines with such liberality as would ensure a no-delay service at all times.

The system of the British Post Office is worked as follows: A subscriber desiring a trunk connexion calls up his local exchange and notifies his requirements. If circuits are available to the town required on such a basis as to afford a no-delay service, the connexion is effected at once and the signalling and control arrangements are similar to those described for junction working. The operator records the particulars of the call on a ticket which is used for future accounting purposes. Should a no-delay service not be available, the operator records particulars of the requirements herself, or, in cases where lines to the town required terminate at a separate trunk exchange, she extends the

subscriber's circuit to the trunk exchange and obtains a direct connexion to a special record operator whose sole business it is to note the particulars of the required trunk connexion. The subscriber is informed that he will be called later and the connexion is then severed. Meanwhile, the ticket is conveyed to the switchboard position where the lines to the town wanted are terminated. Calls at this point are dealt with in order of priority as recorded by the time on the ticket when the demand was initiated. Particulars of the connexion wanted are passed to the distant operator, who extends the circuit direct to the line of the "wanted" subscriber, when such lines terminate in the same exchange, or extends the circuit to a junction, when the "wanted" subscriber is connected to another local exchange, and requests the operator at that exchange to effect the connexion. The trunk operator at the originating town simultaneously effects the connexion direct, or where another local exchange is concerned, by the medium of a junction, to the initiating subscriber, and when both subscribers are on the line, she completes the connexion. The call is controlled by the trunk operators, the junction circuit being equipped in such a manner that the subscriber's signals appear at the trunk exchanges, from which point disconnecting signals are sent automatically to the local exchanges when the connexions between the trunk and the junction circuits are removed.

Trunk exchanges are equipped with relays and lamps for signalling purposes. "Calculagraphs" are employed for stamping the time of commencement and completion of conversation on the tickets. There is also associated with each trunk connexion a device which lights a lamp as soon as the scheduled limit of the period of conversation is reached.

Where the volume of traffic over any route is considerable, the requirements to the distant town may be notified over a separate circuit reserved for the purpose, and the local connexions involving the use of junction circuits to other local exchanges can be established in advance, thus minimizing the time of occupation of the main circuits and securing the greatest possible effective use of the trunk lines.

Manual Exchanges.—The main features of the manual telephone system remained in 1921 what they were in 1910. Improvements had been introduced to some extent, to diminish or eliminate altogether portions of the operator's work, but common battery transmission and signalling, connecting by means of plugs, flexible cord conductors and jacks, lamp calling and supervisory signals—all these remained unaltered.

Among the improvements referred to may be mentioned Keyless ringing, automatic listening, secret service; ringing tone, automatic ringing cut-off; traffic distribution; ancillary answering jacks.

1. **Keyless Ringing** is the feature of a cord circuit which provides that the ringing of the required subscriber's bell commences automatically on the operator connecting to his line and ceases automatically on the removal of the receiver from its rest by this subscriber. This renders unnecessary the provision of a key for ringing purposes—hence the term "keyless" ringing.

2. **Automatic Listening** is a feature which eliminates the listening key. The operator's telephone is automatically connected to the calling subscriber's line when the answering plug of the cord circuit is inserted in the answering jack of that line. The operator's telephone is later automatically disconnected when, after ascertaining the number required by the calling subscriber, the operator connects the calling plug to the line of the required subscriber.

3. **Secret Service** follows from 2. Automatic listening involves the feature that while conditions suitable for conversation are established the operator's telephone is disconnected—and without the aid of a listening key it is impossible for the operator to listen to a conversation.

4. **Ringing Tone** is a tone (distinctive from that intimating to a calling subscriber that the line he requires is engaged) applied to the calling subscriber's line while the bell of the called subscriber is being rung. Hearing this tone, which intimates that the bell of the called subscriber is being rung, and receiving no reply after a reasonable period, the calling subscriber infers that his correspondent is not available and restores his receiver. This facility reduces the time spent on "no reply" calls, by both operator and subscriber.

5. **Automatic Ringing Cut-Off** provides that the ringing of the required subscriber's bell automatically ceases when the calling subscriber, receiving no reply, decides to abandon the call and restores his receiver to its rest.

6. *Traffic Distribution.*—By means of selecting mechanism the line of a calling subscriber is automatically connected to a disengaged operator's position. This avoids the overloading of any operator and at the same time gives all operators a fair load during busy periods.

7. *Ancillary Jacks.*—Additional calling lamp signals and answering jacks associated therewith placed at different parts of the switchboard. When a subscriber calls, signals are displayed at two or more operators' positions, thus increasing the number of operators who may answer. The object of the arrangement is to provide for the more even distribution of traffic and thus to reduce the answering time of the operators during the rush periods.

Automatic Systems.—The idea of automatic telephony is to substitute for the operator of the manual exchange an electro-mechanical or other switching system, which, controlled in its movement by the action of the subscriber, will automatically select, connect and disconnect circuits as desired. The process of machine switching consists of successive group selection. Exchange switching machines are provided and are placed under the control of subscribers or operators. Considering only the former case, the machines are operated by impulses originating in a subscriber's telephone. The standard impulse now in general use is a disconnection of the subscriber's loop (the loop having been closed in the first instance by the lifting of the subscriber's receiver). The train of impulses corresponds to the digit signalled. For instance, the signalling of the digit 7 would constitute a series of seven disconnections of the subscriber's telephone loop as indicated in fig. 1. It will be seen that a complete impulse is 57 % of the total cycle.

FIG. 1.

When the impulses are passing at the standard rate of 10 per second, this gives an electrical condition at the exchange of sufficient duration to effect reliable operation of the equipment.

On the base of the automatic telephone instrument a circular device, known as the dial, is provided for transmitting the impulses. Fig. 2 shows a full view of the face of a dial that has

FIG. 2.

been designed for use in large cities. It will be seen that there are 12 holes each of which corresponds to a digit, also that eight of the holes contain letters. Dealing first with the digits, the method of operation is for the subscriber to lift his receiver and then if he requires to call "7146" he will operate these digits in turn. To call 7 he will place his finger in the hole

corresponding to that digit, rotate the front plate of the dial which is free to move in a clockwise direction until his finger and the finger hole for 7 reach the finger stop shown on the right-hand side of fig. 2. He will then withdraw his finger and the free plate of the dial will return to normal under the influence of a main spring, in doing which the mechanism of the dial will disconnect the subscriber's telephone loop seven times. He will now insert his finger in the hole corresponding to the digit 1 and proceed as before. The impulses passing from the dial will, as has been stated, be transmitted at the rate of 10 a second, and, as will be seen from fig. 1, the short current between the impulses, is only 43 % of the cycle. An appreciable interval, by comparison, must occur between the trains corresponding to each digit because the process of manipulating the dial cannot be performed rapidly enough for it to be otherwise.

In practically all automatic systems the impulse circuit is as indicated in fig. 3, from which it will be seen that the operation

FIG. 3.

of the switching mechanism is controlled by the falling back of a relay armature at the exchange.

The mechanism at the exchange is so designed that by the provision of a sluggish relay or equivalent device certain controlling connexions remain unchanged throughout the whole of the train of impulses, but the long current corresponding to the period between two trains is utilized for effecting a change-over so that each train operates a separate switching device. Briefly the effect is to produce successive selection as already indicated. The operation of the digit 7 in a typical case would operate the mechanism so that an idle outgoing connecting line of the 7th thousand is found. The following digit, 1, will pick out an idle outgoing connecting line to the 1st hundred in the 7th thousand being the 71st hundred. At this point it is common practice to give the subscriber connexion with a switch that can select any one of the 100 lines in the group, so that the next two digits 4 and 6 will call line 46 in the 71st hundred, viz. line 7146.

Automatic systems may in the main be roughly placed in two classes: (a) direct impulse systems, (b) stored impulse systems.

In the direct impulse system may be placed the systems of The Automatic Electric Co., Siemens Bros. & Co., The North Electric Co., and The Relay Automatic Telephone Co. (including licensees of the firms concerned).

The Automatic Electric Co. and Messrs. Siemens Bros. & Co. manufacture what is known as the "Strowger" system, the switches of which in operating utilize two motions, first, a vertical action in which the brush is not making contact followed by a rotary action in which the brush is either hunting for an idle connecting line in the case of a preliminary switch or moving towards the contact of the wanted subscriber's line in the case of a final switch. Two magnets are involved in this operation. There is a third magnet used for effecting the release at the end of the conversation, the operation of release consisting in the restoration of the moving element to normal, first in a rotary direction by means of a main spring and, secondly, in a vertical direction under the influence of gravity.

Fig. 4 shows the elementary circuit connexions for one of these systems. The calling subscriber on lifting his receiver operates relay "LR" which in turn operates "RR." The impulses are received on "LR" whose armature falls back for each impulse placing an earth connexion intermittently on the circuit of "S" and "VM." Both "RR" and "S" are sluggish relays that release slowly so that the succession of "breaks" and "makes" from the impulses do not affect them. When the long current between two trains of impulses occurs the circuit of "S" is disconnected for a period which is long enough for its operation, and "S" electromagnetically operates the switch "SS" so that "VM" is thrown out of circuit and "RM" is substituted. "VM" is the magnet which operates the vertical stepping by means of a ratchet and pawl device. "RM" similarly effects the rotary stepping. The next train of impulses will clearly operate "RM" after which the change-over devices depending on "S" are made to cut out the accessory mechanical apparatus, leav-

ing only the connexions suitable for giving the engaged signal, ringing the subscriber, and talking. At the end of the conversation the caller hangs up his receiver, the armature of "LR" falls back permanently, "RR" is deenergized and the release magnet "REL" is operated thus restoring the switch to normal. "REL" disengages a detent which permits a coiled spring to restore the wipers or brushes in a rotary direction after which gravity carries them vertically to their home positions at which stage the "REL" circuit is opened at "ON." The transmission system consists of two relays "LR" and "LC" associated with two condensers as shown at the top of fig. 4. This will be recognized as the "Stone" C B system (see 26.552).

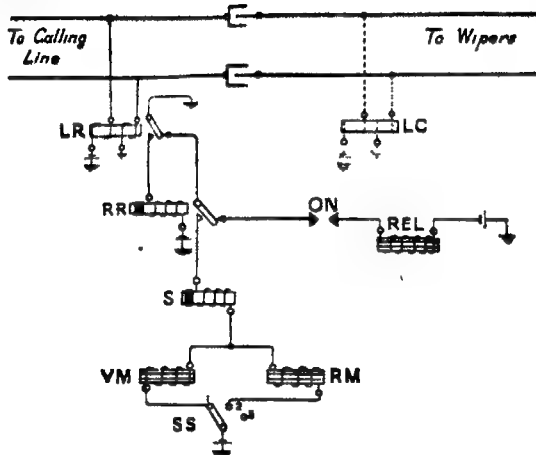

FIG. 4.

The North Electric Co. manufactures a switch operated by direct impulses in which the motions are the reverse of the systems just described. Rotary action, with the brush away from the contacts, is followed by "trunk" hunting in a vertical direction. This permits of vertical contacts which are less liable to the adverse influence of dust than horizontal contacts, and would also permit of a larger number of trunks than 10, being placed in one group without seriously interfering with the design of the equipment.

Both the Relay Automatic Telephone Co. and the North Electric Co. manufacture automatic systems which do not use mechanism as usually understood. The systems consist of aggregations of relays, combined so as to provide a number of connecting or "trunking" paths through the equipment. In the case of the Relay Automatic Telephone Co.'s system the calling subscriber operates his dial in the usual way and at the same time finds an "outgoing" trunk. His impulses operate relay devices known as the "recorder" and the "marker," which latter places an electrical condition on the called subscriber's line so that it immediately operates somewhat like a called line, and finds an idle "incoming" trunk which is placed in communication with the outgoing trunk already seized by the calling party. These two trunks are automatically placed in contact and together form the connecting link for the conversation.

The earliest practical stored impulse system is the "Lorimer" system as used at Hereford (England). In this case the dial as already described is not used, but a lever device is associated with each telephone. The levers are set in definite positions corresponding to the number to be called, and the switches at the exchange are set in motion by the subscriber operating a subsidiary crank that forms part of the calling device. The operation of this crank also winds up the mechanism of the calling device so that the operation of the switches on the exchange can electromagnetically release the calling device and run it down. The running down of the calling device in conjunction with the operation of the exchange switches controls the action of the latter by means of an electrical circuit established through the setting of the levers so that the exchange switches are made to trunk, hunt and find lines in a manner corresponding to the lever setting. The mechanism at the exchange is driven by a motor and can therefore be provided with robust contacts. A subsidiary device known as a pilot switch can be made to operate and alter the connexions between digits or at any other stage of the call so as to control the sequence of switching operations.

The Western Electric Co.'s rotary and panel type systems possess the obvious advantages to be derived from storing connexions and the interpolation of controlling operations at any stage of a call. In both these systems the subscriber's telephone is equipped with a standard dial, and the impulses are taken up by the sender storing device at the exchange. This device is set into position by the impulses and subsequently controls the action of the selective switches in a manner somewhat similar to that indicated for the Lorimer system above mentioned. In the Western Electric Co.'s

systems banks of contacts for 200 and 500 lines respectively are employed, as against 100-line banks for direct-impulse systems, so that the number-storing device is also required to perform the functions of a numerical transformer changing the call record from the decimal system as dialled into whatever system is necessary for the correct operation of the switches. An additional feature associated with the panel system of the Western Electric Co. is the provision of a translator which consists of a cross-connecting device so arranged that any number dialled can be converted from time to time into some other number. This is particularly desirable in the case of large cities in which the selection of exchanges is effected by means of a code. It will be seen on reference to fig. 2 that eight of the finger holes have in addition to the digits a group of three letters. These are arranged in alphabetical order from A to Y omitting Q. The use of these letters is to facilitate the calling of subscribers in areas where manual telephones coexist, and where in the ordinary course very cumbersome numbers would otherwise be involved. The arrangement provides a means of facilitating the conversion of an existing manual area to automatic working. The number "Mayfair 2148" is printed in the directory "MAYfair 2148," and so long as any manual exchanges in the area exist the numbers would be passed in the ordinary way, but as automatic exchanges are introduced the subscriber will obtain connexion by dialling "MAY 2148." It will of course be recognized that to dial MAY is really to dial "629," and the switching equipment must be such that the dialling of this code will give the subscriber connexion to an idle junction circuit outgoing to the Mayfair exchange whether that exchange be an automatic or a manual one. Owing to variations in traffic the size of the junction groups to Mayfair will vary from time to time, and redistribution of junction lines in the automatic equipment will be essential. The translator mentioned provides the means whereby this can be effected, because the transformation by means of the "impulse cross connexion field" will make it practicable for "MAY" to be reconverted into any combination of the 10 digits when taken three at a time.

The traffic problem involved in the provision of connecting circuits or trunks at automatic exchanges is one of considerable interest and importance, as is illustrated by the extent to which it figures in the bibliography appended.

Wire Plant—If the distribution to the subscribers is underground throughout, the main cables are now subdivided into smaller units, bifurcated or multiple branching joints being made between the main and subsidiary cables. The latter cables are accessible in footway boxes, and are terminated in such a way that one or more pairs of conductors can be led direct into any adjacent premises by a small lead-covered paper-core cable. The end of the small cable in the subscriber's premises is terminated in such a manner as to prevent the ingress of moisture.

If, however, the distribution is by means of aerial wires from a pole which is erected to serve a small zone, the cable is continued to a point about 2 ft. below the lowest arm of the pole, and is terminated in a solid or sealed joint from which separate lead-covered leads extend the pairs of conductors to insulators.

For long-distance service up to about 1900 the wires were erected on pole lines along roads, railways and canals. The hard-drawn copper wire of high conductivity (invented by T. B. Doolittle in 1877) is invariably used, and wires weighing from 150 to 800 lb per mile have been employed. It was necessary to carry the long-distance lines through underground cables in the approaches to large English cities, but owing to the inefficiency of cable wires as compared with aerial wires for speech transmission, the length of underground cable sections was kept down to a minimum. As the long distance service expanded and the number of lines increased it became increasingly difficult to find routes for new pole lines, especially near large cities, and the need for improvement in the efficiency of cable wires became a very pressing matter.

The disadvantages of the earlier types of underground cables as compared with aerial lines were: (a) much greater attenuation and distortion of telephonic currents; (b) inability to superpose a third circuit, known as a "phantom," on each pair of physical circuits.

Towards the end of the 19th century Oliver Heaviside had proved mathematically that uniformly distributed inductance in a telephone line would diminish both attenuation and distortion, and that if the inductance were great enough and the dielectric conductance not too high the circuit would be distortionless, while currents of all frequencies would be equally attenuated. Following up this idea Prof. M. I. Pupin showed that by placing inductance coils in circuit at distances apart less than half the length of the shortest component wave to be transmitted, a non-uniform conductor could be made approximately equal to a uniform conductor.

Pupin's system of "loading" telephone conductors has been applied in England mainly to underground cables, and many im-

provements have been made in recent years, so that it is now possible to obtain the same transmission efficiency from an underground telephone circuit as from an aerial circuit of equivalent gauge. The difficulties encountered in working underground cable circuits were exhaustively investigated by the British Post Office in the first decade of this century, and it was proved that the inability to obtain phantom circuits was due primarily to want of balance between the electrostatic capacity of conductors in respect to (a) other conductors and (b) to earth. As a result of the earlier investigations the method of laying up the conductors in pairs to form a complete cable was radically changed. A type of cable known as the "quadruple pair" was introduced. In this type the conductors are lapped with insulating paper twinned together in pairs, and are arranged in "cores" each containing four twisted pairs laid up together around a centre, usually of yarn, forming a "quadruple pair" core. The cores are laid up together to the number required

FIG. 5.

and sheathed with lead. This type of cable was a great improvement on the earlier "twin" cable, and permitted the formation of a superposed "phantom" circuit on two physical circuits. Diagonal pairs in the same core are selected for superposing.

In a later type of cable known as the "multiple twin cable" the centre of yarn is dispensed with, and the cable consists of a number of 4-wire cores made up of two 2-wire cores twinned together. The manufacture of this type of cable has been greatly improved in recent years, and cables are now produced with very small out-of-balance capacities between wire and wire, and between wire and earth. It is still, however, necessary to balance the cables after laying by a systematic method of jointing contiguous lengths, whereby conductors are selected and jointed in such a manner as to secure maximum uniformity of characteristics.

A method of loading the phantom circuit in telephone cables was invented by G. A. Campbell and T. Shaw in the United States and patented in Great Britain in 1911. This method was applied to a cable laid between London and Birmingham in 1914 and extended to Liverpool in 1916.

The phantom circuit is obtained by means of specially wound transformers joined across the ends of the physical circuits. The cores of these transformers consist of a ring made up of very fine soft iron wires. Fig. 5 illustrates the method of connecting

Telephone Repeater.—The art of long-distance telephony was advanced a further and more important stage by the introduction of a practicable type of telephone relay or repeater in 1913.

FIG. 6.

The conception of a repeater which could be inserted in a telephone circuit and fulfil the same functions as a repeater in a telegraph circuit is almost as old as the telephone itself. Early attempts at a solution of the problem were invariably in the form of a sensitive microphone attached to the reed or the diaphragm of a receiving apparatus, but the fundamental defects of repeaters of this type, due primarily to the inertia of moving mechanical parts, prevented their successful application in commercial service. It was not until the development of the 3-electrode thermionic tube had reached the stage of commercial production for wireless telegraphy purposes in 1913 that the problem of the telephone repeater could be solved. Since that time progress has been so rapid as to cause almost a complete revolution in long-distance telephony.

A modern telephone repeater for insertion at an intermediate point in a long telephone line consists essentially of two thermionic tube amplifiers, one for the up and one for the down side of the line circuit, associated with apparatus for balancing the line circuits for duplex working, the telephone circuit being necessarily a duplex circuit. The general arrangement is shown in fig. 6.

The telephone repeater may be used to extend the range of speech over existing lines, as for instance a London-Paris line may be extended by a repeater at Paris to any distant city in direct communication with Paris, a second repeater at the distant city may relay the line again to a further point and so on. In fact it may be said that telephonic speech is now possible over any length of wire circuit. Speech through submarine cables is, however, still limited to comparatively short distances.

The most important application of the telephone repeater, and one in which the greatest economies are possible, is in the internal communications of a country. For instance, in order to provide telephonic communication between, say London and Manchester, Leeds, Newcastle and Glasgow, it has hitherto been necessary to erect line conductors weighing on the average 600 lb. per circuit mile. A London-Newcastle line thus requires about 180,000 lb. of copper. It is now possible by using four telephone repeaters at intermediate points between those two cities to provide equally good communication over conductors weighing only 80 lb. per circuit mile, and these conductors may be contained in an underground cable which will carry 240 circuits. The combination of telephone repeaters with underground cables affords a service of greater efficiency than can be obtained from heavy aerial lines, and a service free from interruption by storms.

Fig. 7 is a plan illustrating a scheme for providing telephonic communication between all the important towns of Great Britain

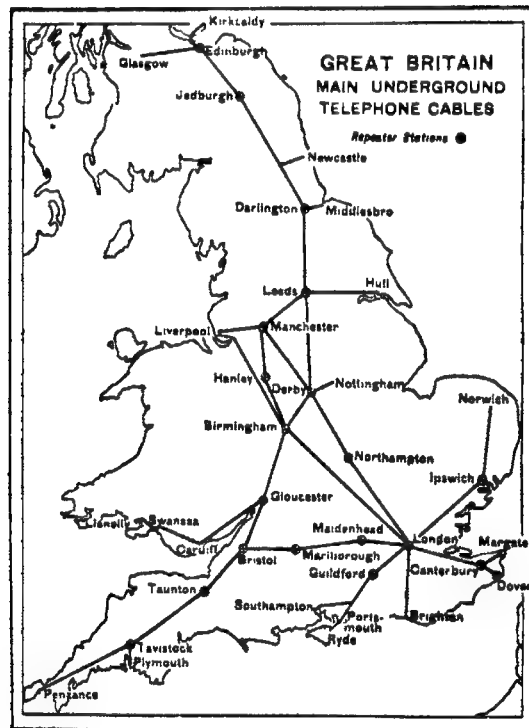

FIG. 7.

by means of underground cables and telephone repeaters. The construction of this extensive system was well advanced in 1921 and was due for completion in 1925.

A list of representative types of main underground telephone cables in Great Britain is given in the table.

Submarine Telephone Cables.—The problem of loading deep-sea cables with inductance coils, and thus increasing the possible range of speech transmission, was successfully solved in 1910, when Messrs. Siemens Bros. & Co. manufactured and laid for the British Post Office between Dover and Calais a 4-core submarine cable loaded with inductance coils at intervals of one nautical mile. The transmission efficiency of this cable was rather more than three times as good as that of a similar cable without loading coils.

In 1911 Messrs. Siemens introduced a form of balata dielectric as a substitute for gutta-percha in loaded submarine cables on account of the greatly reduced leakage of the former as compared with the

‡ In course of construction.

latter. The effect was to reduce materially the attenuation constant and increase the range of speech in loaded cables.

The improved dielectric was used in a cable laid in Aug. 1912 between St. Margaret's Bay, Dover, and La Panne, Belgium. This cable contained four copper conductors, each weighing 160 lb per nautical mile and insulated by a dielectric weighing 150 lb per nautical mile (as compared with 300 lb per nautical mile in the 1910 Anglo-French cable). The variation of attenuation with frequency is much less in the 1912 cable than in the earlier one.

The Anglo-Belgian cable had another special feature, namely, the provision of loading coils for a third circuit superposed on the two physical circuits. The loading coils for all three circuits were placed together at intervals of one nautical mile.

A similar cable with some further improvements in dielectric and loading coils was laid across the Irish Sea between Nevin, Carnarvonshire, and Howth, co. Dublin, in 1913.

A submarine telephone cable of the continuously loaded type was laid across the English Channel by the French Government in 1912, between the same points as the 1910 coil-loaded cable. The weight per nautical mile of dielectric is the same in both cables, but each copper conductor of the former weighs 300 lb per mile as compared with 160 lb per mile in the latter. The transmission efficiency of the cables is practically equal, but the continuously loaded cable provides an additional circuit by superposing. Experiments conducted on this cable in 1914 proved the possibility of obtaining four circuits from a continuously loaded 4-wire submarine cable by introducing an improved method of balancing the electrostatic capacity of the conductors. The fourth circuit has not yet been successful in a coil-loaded cable.

Several additional coil-loaded telephone cables were laid across the English Channel during the war period. Details of these cables are given in the Table.

With equal weights of conductor and dielectric, the relative transmission efficiencies of (a) coil-loaded and (b) continuously loaded 4-wire submarine cables are as 100 to 75, but the latter may provide four circuits as compared with three in the former. Experience has shown that the maintenance and repairs of coil-loaded cables are attended by difficulties which are not met with in continuously loaded cables.

The introduction of telephone relays has made it possible frequently to use submarine cables of a less efficiency than the coil-

loaded cables previously required. Consequently, it is practicable to increase the use of continuously loaded cables, and the modern tendency is in that direction. (W. No.)

UNITED STATES

The more important improvements made in the United States during 1910-21 are briefly described below.

Exchange Cables.—Improvements in the design and the methods of manufacture of cables for use in local exchanges made it possible greatly to increase the number of wires of a given size in a sheath of given size. By employing wires of smaller diameter than those heretofore used the maximum number was still further increased. Cables containing either 900 wires No. 19 A.W.G. (.0359 in. diam.), 1,800 wires No. 22 A.W.G. (.0253 in. diam.), or 2,400 wires No. 24 A.W.G. (.0201 in. diam.) were extensively used in 1921. The improvements which rendered practicable these cables of maximum diam. have been employed also in cables of fewer pairs, thus enabling their diams. to be decreased and their costs reduced. Cables containing the smaller sizes of wire were used as extensively as was justified by their economic balance in relation to other portions of the plant. This resulted in the employment of considerable amounts of No. 24 A.W.G. conductor cable.

For a long time cable sheaths were made of lead alloyed with about 3% of tin, unalloyed lead not having the requisite strength and resistance to corrosion. Extensive research, directed toward finding a cheaper but no less effective alloy, resulted in 1912 in the adoption of lead alloyed with a small amount of antimony. Readjustments in the thicknesses of sheaths and in the composition of the insulating and binding paper produced still further economies.

Loading Coils in Exchange Service.—Many thousands of trunk circuits in multi-office exchanges and circuits connecting large cities with suburban points have been equipped with loading coils, pro-

British Submarine Telephone Cables.

viding transmission of such a grade as would require from 5 to 10 times as much copper in the cable circuits if loading were not employed. Loading coils have been materially improved by constructing the cores of several rings, each of which is made by compressing finely divided particles of iron with a binding material which acts as insulation between the iron particles. There may be as many as thirty thousand million of these particles in the core of a cable loading coil. These cores are more uniform and stable than the wire cores formerly used and are much less affected by excessive currents which may accidentally come into the circuit.

Long-Distance Telephony—Open Wire.—At the beginning of the decade 1910-20, the limits of telephone transmission were about 1,200 to 1,500 m. in open wire. These limits were extended rapidly so that in 1921 practically all parts of the continental United States were placed in communication with each other over distances of 4,000 m. and upwards, employing overhead wires no larger than those used to give the restricted service of 1910. These improvements were made with only slight changes in the lines and equipment and with no change whatever in the subscriber's station apparatus. They depended upon the development of satisfactory repeaters with their associated apparatus and methods of use. The form of repeater generally employed in 1921 was the 3-element thermionic tube. Devised primarily for radio purposes, it was so adapted as to become a remarkably effective repeater. This required that a large amount of auxiliary apparatus be invented and developed and methods devised for balancing the lines and making them suitable for the operation of this apparatus. The amplifier or repeater receives the minute attenuated telephone currents and sends out currents of exactly the same form but greatly enlarged. The transmission gain which may be obtained with vacuum-tube amplifiers in two-way operation depends on the electrical conditions of the line in which the amplifiers are used. This has a great effect on line design.

Transcontinental Telephony.—By the development of methods by which the loading coil could be applied to the heaviest gauge wires and such wires, when equipped with loading coils, could be operated on the phantom principle, it became practicable, in 1911, to provide telephone service between New York City and Denver, Col., and greatly to improve the transmission of speech between cities less far apart. By the application of the phantom principle to such circuits the available facilities were largely increased so that, between the important telephone centres, notable improvements in service were accomplished. On Jan. 25 1915, the transcontinental line of the Bell System was formally opened for business and after that time commercial service was given between the cities on the Atlantic Coast and those on the Pacific Coast. The service in 1921 was handled over a group of 4 non-loaded wires equipped with telephone

repeaters. By using the 2 side circuits and the phantom circuit formed by these wires, 3 simultaneous transcontinental connexions may be established. By means of the addition of compositing apparatus to the circuits the 4 wires which carry 3 telephone circuits also carry 4 telegraph circuits. These 4 telegraph circuits may be arranged to transmit 8 simultaneous messages. The line from New York City to San Francisco is 3,400 m. in length.

Long-Distance Telephony—Cables.—By 1906 a cable 90 m. long was successfully operated between New York and Philadelphia, but, in the then state of the art, that cable could not be used for connexions extending beyond New York or Philadelphia. In 1911, an underground cable was designed capable of giving a satisfactory conversation between Washington and Boston. By 1912, a section of this new cable was laid from Washington to Philadelphia, there connecting with the earlier type of cable to New York. During 1913, a section of the new cable was laid between New Haven and Providence, connecting at New Haven with an earlier type of cable extending to New York and connecting at Providence with an earlier type extending to Boston. Although talking over the whole distance from Boston to Washington was not possible so long as stretches of cable of the older types had to be employed, yet by using the underground in connexion with the overhead, the seaboard cities from Washington to Boston could no longer be isolated by storms destroying the overhead lines. During 1913, the advances in the art of loading and balancing underground circuits together with the repeater developments made it possible to talk satisfactorily by underground wires from Boston to Washington, a distance of 455 m. even though 47% of the total cable in the line was of the types formerly suitable for short-haul working only. In 1912, talking by underground wire for the first time between New York and Washington represented the longest distance achieved. By 1913, this distance had been doubled. The Boston-Washington cable was several times longer than any other in the world. There were in 1921 several cables working along the Boston-Washington route. During 1919, the extension of the toll cable system from Philadelphia to Harrisburg, Pa., was completed. Taken in combination with the cables already working between Boston and Washington, this gave a through toll cable route from the important points on the eastern seaboard as far west as Harrisburg. In 1921, this cable was extended from Harrisburg as far W. as Pittsburgh, a distance of 192 m. from Harrisburg and 304 m. from Philadelphia. For the greater portion of the distance the cable was supported actually on poles. The composition of this cable was as follows:—

Section	Quads No. 16 A.W.G.	Quads No. 19 A.W.G.
Harrisburg-Ligonier	16	125
Ligonier-Pittsburgh	19	120

At the intervals of about 60 m. substantial brick buildings were erected for use as repeater stations to house the equipment, apparatus, power plant and test boards that make up a modern repeater station. General plans were completed for extending this cable from Pittsburgh to Chicago.

The installation of these toll cables resulted in economies due not only to the reduced annual charges on additional circuits as required and less expense for routine maintenance, but also to the fact that the losses resulting from storm damage to open wire were avoided, as were also losses in revenue and reaction on the service during storm periods. Much is thus done to stabilize the toll plant and reduce expenditures as well as further to improve the service. By means of the improvements which had been made it became possible to carry on satisfactory talks over wires in cables more than 2,000 m. in length (where commercial conditions justify such cables) and this was accomplished with practically no more copper in each circuit than had been used in the earliest forms of cable which, as lately as 1882, caused serious interference with transmission when employed in lengths of only a fraction of a mile.

Repeater development reacted on the loading art, requiring the development of loading coils of great magnetic stability and uniformity. Such stability is also particularly important on long circuits which are composited for telegraph operation in order to prevent the telegraph from interfering with the telephone transmission. Although these loading and repeater developments greatly extended the use of cables for long-distance transmission they made it imperative to keep open-wire circuits as free as possible from cable in order to prevent the electrical irregularity thus introduced from reacting on the repeater operation.

Submarine Cables.—In 1921, telephone communication was established with Cuba by means of submarine cables connecting Havana with Key West. These cables brought all of the principal places in the United States into telephonic communication with Havana and other important places in Cuba. There were in 1921 3 cables, each about 115 m. in length. Except at the terminating points, the cables were laid some miles apart in order to minimize the danger of simultaneous interruption as the result of accident. The average depth was about 3,000 ft. and in some places depths of more than a mile were reached. The main portion of each cable had a single conductor, two conductors being employed in the shore ends. The main conductor weighed 350 lb. per m. and consisted of 7 strands of copper wire. The conductor bore a wrapping of fine iron wire, this being covered with gutta-percha enclosed in copper tape which served as a return grounded conductor. By the use of multiplex methods each cable handled simultaneously one telephone and two telegraph messages. Each cable is expected ultimately to handle two or more additional telegraph messages. The use of single conductor cables, the telephone amplifiers, the terminal telegraph apparatus, and the devices for permitting the telephone and telegraph to operate simultaneously, all differed from earlier practice.

The largest submarine cable equipped with loading coils in 1921 was that which crossed Raritan Bay from Staten Island to New Jersey. It was upwards of 28,000 ft. in length, was loaded at 5 points and contained 37 quads of No. 16 gauge wires and 12 pairs of No. 22 gauge test wires. Each loading pot was approximately 16 ft. long and weighed 4 tons. The cable was laid in shallow water, the average depth being 10 ft. at mean low tide.

Carrier Current Telephony.—From the earliest days of the telephone and telegraph there were many attempts to develop multiplex transmission of messages. It was while working on the problem of multiplex telegraphy that Dr. Bell had his first conception of the structure of the original telephone. The long series of inventors, scientists and engineers who have contributed to the development of the multiplex art includes Gray, Edison, Mercadier, Pupin, Hutin, Leblanc, Stone, DeForest, Vreeland, Ruhmer, Squier, Wagner and others. In 1918 research experts and engineers of the Bell System completed the development of a commercial multiplex telephone and telegraph system and put it into operation between Baltimore and Pittsburgh. By means of this multiplex system, 4 telephone conversations may be had simultaneously over one pair of wires in addition to the telephone conversation provided by the ordinary methods. Thus, over a single pair of wires, 5 telephone conversations are simultaneously operated, each giving service as good as that provided by the circuit working in the ordinary way.

In telegraphy, as compared with the ordinary duplex telegraph circuit, this multiplex system permits at least a tenfold increase in messages. Although the commercial installations in use in 1921 provided only 4 additional conversations, the limitations as to number of telephone or telegraph messages on a single circuit were determined entirely by economic considerations. The operation may be considered to consist of combining the telephone current with high frequency current, transmitting this combination over a line wire, and, at the receiving end, removing the high frequency current and leaving the telephone current. The high frequency current serves as a "carrier" for the telephone current over the line.

Simultaneous transmission of several telephone currents is accomplished by means of selective apparatus by which one particular receiving channel is made easily receptive to one particular set of high frequency currents and, at the same time, acts substantially as a

barrier to the currents of other high frequencies which are carrying telephone conversations other than those which the channel in question is designed to receive.

The operation involves the following steps: (1) Generation of carrier current, (2) Modulation, (3) Demodulation, (4) Separation of channels by selective circuits, (5) Repeaters for amplifying currents of carrier frequency at intermediate points.

(1) **Generation of Carrier Current.**—Carrier currents of various frequencies are for convenience obtained from well-known forms of vacuum-tube oscillators. In general the telephone multiplex frequencies run about 10,000, 15,000, 20,000 and 25,000.

(2) **Modulation.**—This term is applied to the process by which carrier current, produced by an oscillator, is so combined with voice currents from a telephone transmitter that the variations of the latter are impressed upon the former. The carrier and voice frequencies are applied together in the grid circuit of a vacuum-tube modulator together with a steady battery voltage.

(3) **Demodulation.**—This is a complementary process of modulation. Modulation may be thought of as elevating the band of essential speech frequencies to a position adjacent to the carrier frequency, and demodulation may be regarded as restoring this band to its normal position in the frequency scale.

(4) **Separation of Channels by Selective Circuits.**—When a number of channels, each employing a different carrier frequency, are operated simultaneously on a common line, each channel must be connected with the line through selective circuits which transmit only the range of frequencies assigned to that particular channel. Not only must the demodulator assigned to a given channel be prevented from receiving, from the line, currents of other channels, but the sending modulator must be prevented from putting on the line currents or frequencies outside of its assigned band. The apparatus specially developed for accomplishing this selection in carrier current telephony are known as "band-pass electrical filters."

(5) **Reaction on the Telephone Plant.**—Carrier currents have imposed new requirements as to transpositions and it has also been necessary to develop new types of loading coils capable of transmitting the carrier frequencies, and also extremely uniform in impedance over the whole frequency range.

Limitations.—From the nature of the apparatus and methods employed, the system is not practically advantageous on short lines. In 1921 it was being applied to lines of 250 m. or more.

Carrier telephone systems were in commercial operation between the following points: Baltimore and Pittsburgh, Harrisburg and Chicago, Harrisburg and Detroit, Boston and Bangor, San Francisco and Los Angeles.

Loud-Speaking Telephones.—By the use of vacuum-tube amplifiers in connexion with specially developed transmitters and receivers, supplemented by large projecting horns, the human voice may be magnified thousands of millions of times so that a public speaker can make himself heard by a vastly greater number of people than ever before. By the use of apparatus and methods of this kind developed by the Bell Telephone System, President Harding's inaugural address in 1921 was heard by over 100,000 listeners standing in an open space of more than 10 ac. before the Capitol.

Radio Telephony.—In 1915 the engineers of the Bell Telephone System succeeded in transmitting speech from Arlington, Va., to the Eiffel Tower in Paris, and, simultaneously, to the Hawaiian Islands in the Pacific Ocean. Two experimental radio telephone transmitting and receiving stations were erected on the Atlantic Coast, one near Asbury Park, N.J., and the other near Plymouth, Mass. By means of these stations, radio telephone communication was maintained between the commercial telephone system and two ships experimentally equipped, plying from Boston to southern ports on the Atlantic Coast.

In July 1920 regular commercial radio telephone service was established between Santa Catalina Is. about 30 m. from shore, and the mainland near Los Angeles, Cal., at the latter point making junction with the local and long-distance wires of the Bell System throughout the United States.

The circuit is provided with through-line ringing of a type which is free from interference and there is a superimposed telegraph circuit capable of forming a link in a duplex wire telegraph circuit. The volume and quality of telephone transmission are so good that the radio link is regularly connected, whenever required, with long-distance wire circuits. On several occasions conversations have been carried on between a steamship on the Atlantic and the Avalon office at Catalina Is. in the Pacific, using the transcontinental wire telephone line as the connecting link overland.

Machine-Switching System.—A retrospective examination of the manually operated switchboard discloses the fact that the tendency of development has been continuously in the direction of increasing the number and extent of the operating functions which are performed electro-mechanically and likewise decreasing the amount of time required of the operator for the handling of the connexion. When a point is reached where the operations performed manually at the central office are eliminated, except in the case of certain special classes of calls, the term "automatic" or "machine switching" is applied to the switching equipment.

There are two principal types of machine-switching equipment, the "step-by-step" and the "panel" type. In both the apparatus

at the central office is set in motion and controlled by a dial, associated with the substation set, and rotated by the subscriber. The "step-by-step" type of equipment makes use of a series of selectors in each of which contact is made by means of a central arm that can be raised to any desired level and rotated, at that level, to the proper one of a series of terminals arranged in the arc of a circle. This type of equipment is mostly used in the smaller cities and for automatic private branch exchanges. The "panel" type of equipment has been developed to a point where it is now being installed on an extensive scale in a number of the larger cities of the United States. On account of its importance a brief description is given.

Panel Type System.—The panel type equipment is so named because the multiple of the selectors is built in panels. The selectors have, in general, capacity for 500 lines or trunks. The multiple of these selectors consists of punched brass strips about 3 ft. long and one in. wide piled one above the other with insulation between. Since 3 connexions are necessary for each line or trunk, 1,500 of these strips are provided. The strips are divided horizontally into 5 groups or panels of 100 lines or trunks each and are mounted on frames having capacity for 60 selectors each, 30 on each side. The selector consists of a tube running vertically, close to the banks, the tube being equipped with a set of brushes for each bank. The brushes normally are held mechanically so that they do not engage the terminals. At the bottom of the tube, a friction clutch is provided which, by engaging constantly rotating shafts, can cause the tube to be raised or lowered. The brushes are multiplied together by wires within the tube, these wires being attached at the top of the tube to feeder brushes which move over insulated feeder strips. The process of selection consists in first mechanically tripping the desired brush into engagement with its multiple bank, next in moving the tube carrying the brushes upward to choose the desired group within the bank, and finally continuing the movement upward to choose the desired subscriber's line or an idle trunk within the selected group. The subscribers' lines appear on the multiple of panel type selectors known as "line finders." The function of the line finder is to make connexion with calling subscribers' lines. It corresponds to the "A" operator's answering cord and the subscriber's answering jack in the manual system. The brushes of the line finder are attached to the brushes of a panel type "district selector" and also to the brushes of a small selector known as a "sender selector." As soon as a calling subscriber's line has been picked up by a line finder, the sender selector

selects an idle "sender" out of a common group. When the calling subscriber dials, the pulses are registered in the sender which controls the setting-up of the connexion and is then freed. The sender may be likened to the operator of the manual system. The sender causes the district selector to choose a trunk to the desired office, or, if more than 500 outgoing trunks from the office are required, causes the district selector to pick out an idle "office selector" of the panel type which selects the desired trunk. The trunk incoming to the full mechanical office ends in the sender of an "incoming selector" of the panel type whose function it is, under control of the sender, to pick out an idle panel "connector" having access to the group of 500 lines in which the called subscriber's line may be found. Controlled by the sender, the connector then selects the called line.

Calls from a machine-switching to a manual office are completed over "call indicator trunks." As the calling subscriber dials his call, the district or office selector picks out an idle trunk to the desired office. This trunk ends in a plug before a "B," or incoming trunk operator in the called office. When a call appears on that trunk, the "B" operator depresses a display key associated with that trunk, whereupon the number which is desired in that office is quickly transferred by the sender to a bank of numbered lamps appearing before the "B" operator, and the "B" operator thereupon plugs the trunk into the desired subscriber's line.

For completing calls from a manual to a full mechanical office "key indicator mechanism" is employed. This is a mechanism which indicates to the "A" operator an idle trunk to the desired office which ends at that office at an incoming selector. The "A" operator by using a small 10-button key-set is enabled to control the incoming selector to make connexion through the aid of connectors with the called line desired.

Other Improvements.—In the United States there is a large and growing use of the telephone for communications essential to the operation of both steam and electric railways. The problem of minimizing the disturbing effect upon telephone circuits produced by induction interference from electric light and power circuits has resulted in careful, coordinated work by the power and telephone engineers. Important improvements have also been made in local and toll line operating efficiency.

Organized research has not only enabled the limits of telephony to be greatly extended but, at the same time, improvements and economies have been made in every department of the business.

Telephone Development of the World—January 1 1910, 1914 and 1920.

(Some of the figures—for the most part those for small places not shown separately—are necessarily in part estimated.)

	Jan 1 1910		Jan 1 1914		Jan 1 1920

TELPHERAGE (see 7.63).—The World War saw, in the Italian army, amazing use made of the system of telpher transport for fighting on the Alps. When, after many years, snow, ice and avalanches will have all but cancelled every trace of the epic deeds performed in those regions, tourists who climb to the crests of the Adamello, the Marmolata, the Tofana and a hundred other peaks will hardly believe that thousands of men lived and fought for years in the very spots that they have reached only with difficulty, with the help of ropes and ice-axes, and in favourable weather.

Before the war it was thought impossible to conduct military operations on the high peaks. It was believed that the ordinary troops would be practically tied to the roads, that a company of "Alpini" with a few mountain guns would be the largest unit that could be used in places where only paths for mules existed, and that the rocky peaks, the snows and the ice, would be reached only by small groups belonging to specialist units, sent there to keep an eye on the enemy.

But from the earliest days of the campaign there happened on the Alpine front something very similar to what had occurred in France after the battle of the Marne, when Germans and French, in their common desire to outflank each other in the direction of the sea, finally reached the sea itself, thus forming one uninterrupted line from the Vosges to the Channel. On the Alps, with the object of capturing or turning the Austrian defensive lines, the Italians climbed higher and higher in ever-increasing numbers, the Austrians doing likewise, until the very tops of the mountains were reached and it became impossible to go farther. The most elevated points of the frontier having been thus occupied, the Italians put themselves in a position to meet enemy attacks as well as to face the inclemency of the climate a hard and relentless struggle which had to be started afresh every time war operations involved a change of positions.

The first days of the war saw whole companies clinging hand and foot to the rocky summits, battalions encamped and freezing at a height of 3,000 metres. Field guns, drills, photo-electric stations were taken to pieces and carried up bit by bit to giddy heights, and there put together again. Food, water, ammunition were carried for many hours on mules, and thence transferred to columns of men who carried them for long hours more. At times the wounded and the sick had to be removed by securing them with ropes and letting them slide down gullies, or by allowing them to be jolted on stretchers along impossible paths. Very often they had to be attended to on the spot, behind a rock, because their condition did not allow of so painful a transport.

Numberless were the cases of men who, barefooted, with daggers in their mouths, would climb up the most impracticable summits during dark and stormy nights, and surprise the enemy where the latter felt sure that the ravines and precipices which surrounded him were his surest guards. Many times whole supply columns were crushed and buried by avalanches and rocks. Avalanches claimed thousands of victims among the troops on march, in hutments or in trenches. In certain places and at certain periods the danger was so great that when the men went out they were supplied with a long thin rope coloured in red. The colour came off with the damp and stained the snow, thus facilitating the search for men buried underneath.

The colossal work done at such great heights originated unheard-of conditions of defence and of existence. In places where until then a hurried visit with an experienced guide seemed a bold feat, in regions where there was perhaps one isolated Alpine hut in which it was considered an ordeal to spend one or two nights, there were constructed hutments, telegraph and telephone offices, infirmaries, workshops and stores. In such places, at a height of over 3,000 metres, tens of thousands of men spent several winters. To prepare these encampments both for shelter and for defence, it became necessary to excavate in the rock an enormous quantity of vast caves. In some places an underground way was cut in the rock with inter-communicating caves

lined with timber and provided with water-pipes, electric lighting, etc. Galleries were excavated in the ice, between the Italian and Austrian trenches, leading under cover to advanced posts or even well into the enemy's lines. Gigantic operations with mines were also carried out. Cutting the rock was rendered possible thanks to the great perfection of the compressed-air drills. During the war the Italians turned out an admirable type of motor-driven air-compressor, which met with success also in the Allied armies. On the Italian front there were 20 large plants for fixed drills and about 4,000 groups of portable drills of from 5 to 45 horse-power. The remarkable skill of the Italian miners facilitated considerably the carrying out of most important and difficult mining operations.

In road-making wonderful results were obtained. Once operations were transferred to the highest and most inaccessible points, where in many cases there was not even the narrowest path, it became an absolute necessity to create means of communication at once. Roads were constructed which allowed heavy artillery and motor lorries to reach points where a few months before only a mountain expert would have trod.

The total length of the roads laid down by the Italian army was in round figures as follows—

1,600 km	of roads for mules
1,100 "	" " " carts
3,100 "	of roads for motor lorries.

But the building of roads could not always meet the requirements of troops operating in Alpine districts. It happened very often that the number of men detailed to a certain point did not justify the building of a road on such difficult ground, or that snow and avalanches in the winter prevented the safe use of means of communication already existing, or that the enemy's fire swept them; or, finally, that the occupation of new positions made it necessary to send supplies out of proportion to the available transport and before there was time to build a road. The difficulty in such cases was skillfully overcome by means of special mechanical transport. Wire railways or "telphers" were provided, thus economizing time, labour and oil, and avoiding congestion of roads. These telphers are a kind of suspension railway. A double metal cable called "bearer" is extended on trestles placed in a straight line at different distances on the sides of the mountain. There are two stations, one at the starting-point and the other at the end of the line. In one of these stations there is a motor which works an endless cable (the "drawer"), to which are fixed two or more small waggons. The cable turns and draws the waggons supported by the "bearer" cable by means of small wheels which run on it.

Different kinds of telpherage plants were used.

1. *Telfors*.—These were provisional lines moved by man power and used in the most advanced zones to supply isolated posts or trenches. Their average length was 500 metres and each could carry about 50 quintals a day.

2. *Dismountable Teleferische*.—These were run by motors and were put up in advanced zones. Their average length was from 1,000 to 2,000 metres, and each could carry from 10 to 20 quintals an hour. They could be dismantled and were portable, and could be installed even where there were no roads. These lines proved most useful for the transport of supplies in newly occupied positions. When in 1917 the troops of the 11 Army crossed the Isonzo and advanced on the Bainsizza (Bainitsa) plateau, they could not communicate with the lines in the rear except by means of the few and had mule-paths; but after only four days a few telphers were already in working order, and on the tenth day there were no less than 12 doing service. Similar miracles of speed were performed in the new mountain positions between the Brenta and the Piave.

3. *Permanent Teleferische*.—These were run by motors and were fixed. They were employed at some distance from the lines, and reached a maximum length of 8,000 metres. They could carry about 150 quintals per hour.

Some permanent *teleferische* were already working before the war for the service of mountain fortresses, and some types of portable *teleferische* had been studied and estimates prepared. Oil and electric motors were in use.

The telphers covered on an average a rise of 650 metres from the starting-point to that of arrival, but in some cases even 1,500. The trestles were often at very great distances from one another and placed on peaks, while the waggons ran over fearful abysses. In the highest regions the lines often ran at a height of 2,000 to 3,000 metres; a few were installed even at 3,500 metres above sea-level.

On the eve of the retreat from Caporetto, in Oct. 1917, 380 *telefors* and 530 *teleferische* were in working order. The former had a total length of 190 km., the latter of 630. During the retreat about 550 *teleferische* and *telefors* were lost or dismantled. At the date of the Armistice there were 270 *telefors* and 460 *teleferische* run by motors. The former had a total length of 170 and the latter of 640 kilometres.

The telpherage lines laid on the Italian front transported in all 33,000,000 quintals, the load of 330,000 railway trucks.

The service was under a special central administration with a competent staff drawn from the telpher transport companies (one for each army). There was also a department for the supply and testing of the material and a depot-school with construction and repairing shops. The bulk of the material was built by private concerns, but set up by the military.

The services rendered by the telpherage lines were invaluable. It was only thanks to these lines that it was possible to maintain positions which the troops would otherwise have been compelled to abandon for want of supplies. They allowed detachments to be kept in almost impossible positions even during the winter, as well as assuring an adequate supply of ammunition for guns placed in the most inaccessible positions which men could not have reached if laden with shells. Thousands of lives were saved when their gently sliding waggons were used for the transport of wounded and sick, who were thus spared a lengthy and agonizing journey to hospital. (M. R.)

TENNESSEE (see 26 610).—The pop. in 1920 was 2,337,885 as against 2,184,789 in 1910, an increase of 153,096, or 7% as against 8.1% in the preceding decade. The negro pop. during 1910-20 decreased numerically from 473,088 to 451,758, and decreased proportionally from 21.7% of the total to 19.3%. The average density of pop. in 1920 was 56.1% per sq. m.; in 1910 it was 52.4. The urban pop. (in places of 2,500 inhabitants or more) increased from 20.2% of the total in 1910 to 26.1% in 1920. Only two cities, Memphis and Nashville, had in 1920 more than 100,000 inhabitants, only two, Knoxville and Chattanooga, had between 50,000 and 100,000. The following table shows the pop. and increase per cent. for the six cities exceeding 10,000 for the decade 1910-20—

	1920	1910	Increase per cent
Memphis	162,351	131,105	23.8
Nashville	118,342	110,364	7.2
Knoxville	77,818	36,346	114.1
Chattanooga	57,895	44,604	29.8
Jackson	18,800	15,779	19.5
Johnson City	12,442	8,502	46.3

Agriculture.—During the decade 1910-20 the interests of the state remained predominantly agricultural. Although the total land area in farms decreased from 20,041,657 ac. to 19,510,856 ac., the improved land increased from 10,890,484 ac. to 11,185,302 ac., and the number of farms increased from 246,012 to 252,774. During the same period the average acreage per farm decreased from 81.5 ac. to 77.2 ac., but the average value per farm increased from \$2,490 to \$4,953, and the value of all farm property increased from \$612,520,836 to \$1,251,964,585. The average value of land per acre in 1920 was \$41.40; in 1910 it was \$18.53. Of the 252,774 farmers in 1920 214,592 were whites and 38,182 were negroes. Of all farmers 148,082 were owners, 103,885 tenants; and 807 managers. Of the total 11,374 were women. The total value of farm crops in 1919 was \$318,285,307, of which amount \$144,778,157, or 45.5%, represented cereals; the total value in 1909 was \$111,133,210, cereals representing 49.8%. The cereal acreage in 1919 was 4,786,373 ac. as against 4,136,647 ac. in 1909, an increase of only 1.2%. The following table shows comparative acreage, production, and value of the important crops for 1919 and 1909—

	Acreage	Production	Value
Corn	1919 3,301,075	70,639,252 bus.	\$127,150,649
"	1909 3,146,348	67,682,489 bus.	45,819,093
Oats	1919 162,417	2,413,409 bus.	2,534,082
"	1909 342,086	4,720,692 bus.	2,378,464
Wheat	1919 684,497	6,362,357 bus.	14,506,174
"	1909 619,861	6,516,539 bus.	6,913,335
Hay and forage	1919 1,751,123	1,907,345 tons	49,649,657
Hay and forage	1909 1,060,480	1,100,838 tons	12,784,783
Cotton	1919 807,770	306,974 bales	48,808,866
"	1909 787,516	264,562 bales	17,966,517
Tobacco	1919 138,561	112,367,567 lb.	24,720,869
"	1909 90,468	68,756,599 lb.	5,661,681

The value of vegetables sold in 1919 was \$27,947,250 and of fruits and nuts \$7,888,912; the values respectively in 1909 were \$10,430,975 and \$4,486,281. Of the chief domestic animals on farms in 1920 and 1910 the number and value were as follows:—

		Number	Value
Horses	1920	317,921	\$35,582,960
	1910	349,700	39,320,044
Mules	1920	352,510	51,042,649
	1910	240,282	32,489,724
Cattle	1920	1,161,846	51,370,208
	1910	996,529	20,690,718
Sheep	1920	364,196	4,021,678
	1910	795,033	3,009,196
Swine	1920	1,832,307	19,477,775
	1910	1,387,938	7,329,622

In 1920 there were 11,835,303 fowls valued at \$10,591,600, and 191,898 hives of bees valued at \$698,258. In 1919 the reported milk production was 115,119,224 gal.; the value of milk, cream, and butter fat sold and of butter and cheese made was \$20,640,849. The office of inspector of apuraries was created in 1911. The Smoky Mountain area (59,213 ac. in Blount and Sevier counties) and the White Top area (33,619 ac. in Johnson and Sullivan counties and Washington co., Va.) were approved for purchase in 1912 by the National Forest Reservation Commission under the Federal Act of March 1, 1911 to preserve upland watersheds. In 1920 254,118 ac. of farm land were reported as provided with drainage and 640,479 as needing drainage. Capital invested in drainage enterprises, Dec. 31, 1919, totalled \$2,925,944. On that date there were completed 777 m. of open ditches and 42 m. of levees, there were under construction 135 m. of open ditches and 10 m. of levees. Most of these enterprises are in the western division of the state, where the tributaries of the Mississippi are utilized. The above figures do not include private supplementary works installed by individual farmers.

Mineral Products.—Tennessee produces most of the copper mined in the southern states. Its entire product of copper, gold, and silver comes from mines worked primarily for copper in Polk county. Lead production, first reported in 1915 (1,660 lb.), amounted to 4,376,000 lb. in 1919. In the latter year gold was valued at \$5,662. The silver output was 98,288 oz., copper 15,623,589 lb., zinc 47,494,000 lb. Because of strikes the coal amounted to only about 5,000,000 tons. The demands of the World War led to the working of known manganese deposits in 16 counties. In 1916 oil was discovered in Scott county, and later some producing wells were drilled. In 1919 the Bankers Petroleum Co. of New York, obtained large tracts of land in Robertson and Dickson counties, a promising shallow-oil field. In 1910 natural gas was found near Franklin. In 1919 the production of phosphate rock was 473,985 tons.

Manufactures.—The product of manufactures remains relatively small, the value of 1914 being less than 1% of the total for the United States. Their growth between 1909 and 1914 was as follows:—

	1914	1909
Establishments	4,775	4,609
Wage-earners	74,373	73,840
Capital	\$211,423,167	\$167,923,784
Salaries	11,828,691	9,186,243
Wages	33,082,987	28,251,591
Cost of materials	123,430,135	104,015,834
Value of product	212,071,489	180,216,548
Value added by manufacture	88,641,354	76,200,714

In 1914 lumber and timber products still led, having a value of \$31,430,208. Flour-mill and grist-mill products were valued at \$26,413,574; cottonseed oil and cake \$11,414,243. There were nine other industries each with a product valued at over \$4,000,000; food preparations; foundry and machine-shop products; general shop construction and repairs by steam railway companies; printing and publishing; hosiery and knit goods; cotton goods; patent medicines and druggists' preparations; fertilizers; bakery products. In 1914 84.6% of the average number of wage-earners were males over 16 years old, 13.6% females, and 1.8% children under 16. In 1909 the respective figures were 85.3%, 11.3%, and 3.3%.

Transportation.—On Jan. 1, 1919 the total railway mileage of the state was 4,083 m., or 9.79 m. per 100 sq. m. of territory. The chief railways were: Louisville and Nashville 952 m.; Nashville, Chattanooga and St. Louis 903 m.; Southern railway 891 m.; Tennessee Central 291 m.; Illinois Central 143 miles.

Finance.—The balance in the state Treasury Jan. 1, 1918 was \$368,818. Receipts for 1918 were \$7,954,650 and disbursements \$7,481,756, leaving a balance, Dec. 31, 1918, of \$841,682. On the same date the total bonded debt was \$11,481,000. On Dec. 31, 1912 the balance in the state Treasury was \$317,270 and the bonded debt \$15,218,600. The number of all reporting banks, June 30, 1920, was 546; aggregate resources \$489,162,000; capital stock paid in \$35,041,000; individual deposits \$312,222,000.

Education.—By an Act of 1909 state normal schools were established in Johnson City, Memphis, Murfreesboro, and (for negroes) at Nashville. In Jan. 1911 Bruce R. Payne (b. 1874) was elected president of the George Peabody College for teachers in Nashville.

Later in the year this college was moved from South Nashville to a new site adjoining the campus of Vanderbilt University. Arrangements were made for an interchange of courses of instruction between the two institutions. In 1918 the total school pop was 790,959. The enrolment in the public schools was 604,633 and the average daily attendance 418,709 (368,888 in 1912). The number of teachers was 11,880, of whom 8,375 were women. In 1919 the compulsory school age was raised from 14 to 16 years.

History.—In 1910 Benjamin W. Hooper (b. 1870) was elected governor, following a serious split in the Democratic party over the prohibition question. He was the only Republican elected to state office, and was the first Republican governor since 1883. He took a strong stand for prohibition. The Democratic Legislature displayed much opposition to the governor, and his inauguration was delayed through lack of a quorum until Jan. 25, 1911. The regular Democrats passed a bill depriving the governor of the power of appointing the state board of elections, and raising the number of members from three to seven. The bill was vetoed by the governor, and to prevent its passage over the veto the Republicans and independent Democrats migrated to Alabama, where they remained until acquiescence in the veto was forced. The governor also vetoed a bill giving \$500 additional salary to each member of the Legislature, but approved an amended bill reducing the increase to \$200. In 1911 the Legislature chose Luke Lea (b. 1879) to succeed U.S. Senator James B. Frazier. In 1912 Hooper was renominated for governor and was reelected over Benton McMillin (b. 1845; governor 1899-1903), the Democratic candidate. Robert Love ("Bob") Taylor (b. 1850), U.S. Senator since 1907, died March 31, 1912. He was a representative in Congress 1879-81, governor 1887-91 and 1897-9, and unsuccessful candidate for governor 1910. He was long a picturesque figure in state politics and widely known as a popular lecturer. In the gubernatorial campaign in 1886 his Republican opponent was his own brother Alfred Alexander ("Alf") Taylor (see below). They stumped the state together, Bob everywhere winning favour by his stories and folk songs and his "fiddle." As his successor to the Senate the Legislature in 1913 chose John K. Shields (b. 1858), a member of the state Supreme Court since 1902 and Chief Justice since 1910. Another prominent politician, James D. Porter (b. 1828), governor 1875-9, died May 8, 1912. In July 1915 the city of Nashville was placed in the hands of a receiver, as the result of the disappearance of the city's cash books covering the period 1908-12, and in 1916 the mayor was removed from office for remissness of duty. In Nov. 1915 the mayor of Memphis, the commissioner of fire and police, and the judge of the municipal court were removed from office for failure to enforce the prohibition law. In the presidential election of 1916 Wilson received 152,955 votes and Hughes 116,257. In 1920 Harding received 219,820 votes and Cox 206,558. For the first time since 1868 the Republican presidential candidate carried the state. A Republican governor also was elected, "Alf" Taylor, brother of the former Democratic governor. Taylor received 229,463 votes as against 182,836 for A. H. Roberts, who had been renominated by the Democrats.

Proposals made by the Legislature to call a constitutional convention were defeated in 1916, 1917 and 1920. In Sept. 1916 a new bridge across the Mississippi at Memphis was opened. An Act prohibiting the manufacture of intoxicating liquor in the state became effective Jan. 1, 1910, in Oct. 1913 Gov. Hooper called a special session of the Legislature and secured passage of the so-called nuisance bill, intended to close every saloon in the state, forbidding the sale of intoxicating liquor within four miles of any school; in 1915 provision was made for removal from office of state, county, or city officials who failed to enforce the prohibition law; on Feb. 2, 1917 Gov. Rye signed a bill forbidding the importation of liquor into the state. The hours of labour for women were reduced to 58 per week after Jan. 1, 1914 and to 57 after Jan. 1, 1915. In 1913 for the first time the reporting of accidents was required, wherever persons were employed; provision was made for enforcing the installation of additional fire escapes in factories; and a department of workshop and factory inspection was created. The same year an Act was passed

providing "that married women be and are hereby fully emancipated from all disability on account of coverture, and the common law as to the disabilities of married women and its effect on the rights of property of the wife is totally abrogated." On April 1 1913 the Legislature ratified the amendment to the Federal Constitution for popular election of U.S. senators. In 1915 a law was passed providing for mothers' pensions. In 1917 the letting of prison labour to private contractors was prohibited, and an Act was passed forbidding the limiting of the output of coal for increasing the price. The same year a State Budget Commission was created, having as its members the governor, the comptroller, the treasurer, the secretary of state, and the auditor. The wilful setting fire to any woods was made a felony. On Aug. 18 1920 the House by 50 to 46 voted to concur in the Senate resolution (adopted Aug. 13 by five to four), ratifying the proposed amendment to the Federal Constitution, providing for woman suffrage. As the 36th state (out of the 48 in the American Union) to ratify, Tennessee brought the number up to the requisite three-fourths. The contest among the legislators was bitter, and there were attempts to rescind the House's action on constitutional grounds. Governor Roberts, however, on Aug. 24, sent certification of the state's ratification to Secretary of State Colby, who on Aug. 26 proclaimed the Federal amendment for woman suffrage to be in effect.

In the World War Tennessee furnished to the army, navy and marine corps 91,386 men. Contributions to the various war loans were as follows: First Liberty Loan \$10,024,800, Second \$26,043,650, Third \$33,783,250; Fourth \$55,867,250, Victory Loan \$37,555,450.

Recent governors have been: Malcolm R. Patterson (Dem.), 1907-11; Benjamin W. Hooper (Rep.), 1911-5; Thomas C. Rye (Dem.), 1915-9; A. H. Roberts (Dem.), 1919-21; Alfred A. Taylor (Rep.), 1921- (G C S)

TENNIEL, SIR JOHN (1820-1914), English artist (see 26.626), died in London Feb. 25 1914.

TERMONDE (see 26.645).—Pop. (1914) 10,138. The town, up to 1906, was still considered one of the five "fortified places" in Belgium, but as the fortifications had not been demolished at the time of the German invasion in 1914 the Belgians decided to defend it. In an early attempt to outflank Antwerp the Germans bombarded and took Termonde, setting fire to it and destroying three-fourths of the town, including the Hôtel de Ville and the spire and vaulting of the 15th Century Gothic church of Notre Dame. The Belgians recaptured the town on Sept. 10 1914; on Sept. 16 the Germans renewed the bombardment and completed its destruction. Von Beseler's army forced the passage of the Scheldt here on Oct. 7.

Rebuilding was being actively carried on in 1921, together with the reestablishment of its industries of rope making, bleaching, wire drawing and cotton spinning. The old Butchers' Hall has been transformed into a museum.

TERRY, EDWARD O'CONNOR (1844-1912), English actor (see 26.660), died in London April 3 1912.

TERRY, ELLEN ALICIA (1848-), English actress (see 26.660), appeared as Mistress Page in *The Merry Wives of Windsor* at His Majesty's theatre, London, in 1911, on the occasion of a special performance to celebrate the coronation of King George V., and made her last regular stage appearance as the Nurse in *Romeo and Juliet*, produced by Miss Doris Keane at the Lyric theatre, London, in 1919. Her sister, MARION TERRY (b. 1856), appeared in H. Vachell's *Fishpingle* at the Haymarket theatre in 1916 and in Tolstoy's *Reparation* at the St. James's theatre in 1919.

TETANUS or **LOCKJAW** (see 26.669).—One of the chief triumphs of preventive medicine during the World War was in the treatment of this disease. The appearance of tetanus in the British army during the early days of the retreat from Mons was so terrifying a phenomenon that immediate steps were taken to cope with it. It had been suggested that the disease might be prevented if a dose of anti-tetanus serum was given as soon as a wound was sustained, for, as is well known, some days elapse before the bacilli, which remain in the wound, are able to secrete sufficient

poison to precipitate an attack. The suggestion was carried out and was immediately successful. From that time every wound, no matter how slight, was followed as soon as possible by a dose of anti-tetanic serum. The War Office set up a committee for the study of tetanus (1914-8) under Gen. Sir David Bruce.

Sir David Bruce later presented to the Research Defence Society a paper dealing with the results of his labours. Out of 1,242,000 wounded men who were sent home to England 1,458 cases of tetanus arose, giving a ratio of rather more than 1 per 1,000. How favourably this general figure compares with earlier ones is shown by the fact that in Sept. 1914 the ratio of tetanus cases to wounds was 9 per 1,000. In Oct. 1918 the ratio was 0.5 per 1,000. Thus the incidence of cases of tetanus in Sept. 1914 was 18 times as heavy as in the last month of the war.

A sudden fall in the incidence took place in Nov. 1914 when preventive inoculation, which was introduced about the middle of Oct. 1914, had begun to exercise its beneficial effects. The following figures giving the number of cases of tetanus per 1000 wounded men make this clear:—

Cases of Tetanus		Cases of Tetanus	
Sept. 1914	9	Feb. 1915	1.1
Oct. 1914	7.3	March 1915	0.4
Nov. 1914	2.3	April 1915	2.3
Dec. 1914	1.4	May 1915	0.8
Jan. 1915	0.0	June 1915	0.2

The same experience was met with in the French and German armies. As soon as preventive inoculation with anti-tetanic

Fig. 1.

serum became a universal practice the incidence of tetanus dropped sharply and remained small. Later in the war, June 1917, it was ordered that each wounded man should receive not one inoculation as formerly but four, at intervals of a week. This was on account of the fact that the minimizing effect of the serum passes away rather quickly.

The effect is not always to prevent absolutely. But even in those cases in which tetanus does supervene in spite of the inoculations the incubation period is lengthened and the death-rate is lowered. It is well known that, other things being equal, a long incubation period tends to result in a milder attack than a short incubation period, thus any circumstance prolonging the incubation period will also tend to lower the death-rate. The diagram, fig. 1 (after Sir David Bruce), shows clearly how successful were the inoculations in lengthening the incubation period.

In other words only 26.9% of the inoculated are attacked during the first fortnight, whereas 68.9% of the uninoculated are attacked. Among the protected 40.0% have an incubation period of more than 35 days; among the unprotected only 6.5%. The average incubation among inoculated is 45.5 days, among uninoculated 10.9 days.

Fig. 2.

Indeed, in each year of the war the incubation period tended to rise, as is shown in the diagram, fig. 2.

Further it was found that the inoculations tended to limit the degree of tetanus, converting what would be generalized cases into local or one-limb cases. The following table illustrates this:—

Tetanus type	Percentages				
	1914	1915	1916	1917	1918
General	98.9	98.6	87.0	76.6	83.5
Local	1.1	1.4	13.0	23.4	16.5

Local tetanus tends to occur in the wounded or injured limb and to be confined to that limb. It is much less severe and far less fatal than the generalized type.

Naturally the death-rate reflected these successes. Among the unprotected and unrecorded the death-rate per cent. was 53.5. Among the protected it was 23.0. The "unrecorded" here undoubtedly include cases which had received a dose. This accounts, in Sir David Bruce's opinion, for the fact that the death-rate is lower than the old pre-serum rate of 85%.

It is thus evident that the method employed during the war fully justified the hopes which were entertained concerning it, and that an immense amelioration of pain and distress was effected. Indeed, when the terrible character of this disease is recalled it will be seen that preventive inoculation did much to support the moral of troops by assuring them of safety, or comparative safety, in the event of exposure to the infection.

See Maj.-Gen. Sir David Bruce, K.C.B., F.R.S., *The Prevention of Tetanus During the Great War by the Use of Anti-tetanic Serum*. (Research Defence Society, Form D2, July 1920.) (R. M. W.)

TEWFIK, AHMED, PASHA (1843—), Turkish statesman, was born in Constantinople in 1843, and in 1859 entered the army. In 1870 he quitted the military service and was attached to the translation bureau of the Sublime Porte. He entered the diplomatic service and acted as political agent for the army of the Danube and the Balkans during the Russo-Turkish War (1877-8). He was subsequently attached to the Turkish legation at Athens, where he later became minister. In 1884 he was appointed ambassador to Berlin, but in 1895 was recalled in order to become Minister of Foreign Affairs. After the Young Turk revolution he became grand vizier (1900), but the same year was sent as ambassador to London. In 1912 he was again grand vizier for a brief period. On the close of the World War (Nov. 1918), during which his sympathies were with the Entente, he became grand vizier for the third time, and formed a Government which excluded all members of the Committee of Union and Progress. He resigned in March 1919, but again became head of the Government on the resignation of Damad Ferid Pasha in Oct. 1920.

TEXAS (see 26 688).—In 1920 the pop. was 4,663,228, as against 3,896,542 in 1910, an increase of 766,686, or 19.7%, as against 27.8% in the preceding decade. The urban pop. (in places of 2,500 or more) was 1,512,689, or 32.4% of the total as compared with 24.1% in 1910. The average number of inhabitants per sq. m. increased from 14.8 in 1910 to 17.8 in 1920. The following table shows the growth of the 10 cities in the state having in 1920 a pop. of more than 30,000:—

	1920	1910	Increase per cent.
San Antonio . . .	161,379	96,614	67.0
Dallas . . .	158,976	92,104	72.6
Houston . . .	138,276	78,800	75.4
Fort Worth . . .	106,482	73,312	45.2
El Paso . . .	77,560	39,279	97.4
Galveston . . .	44,255	36,981	19.7
Beaumont . . .	40,422	20,640	95.8
Wichita Falls . . .	40,079	8,200	388.8
Waco . . .	38,500	26,425	45.7
Austin . . .	34,876	29,860	16.8

Agriculture.—The 1910 census gave Texas 417,770 farms, with a total area of 112,435,067 ac., of which 27,360,666 ac. were improved. Owing to the fact that in 1900 the large ranches in the western part of the state were included under farm acreage, there was a decrease in the farm acreage between 1900 and 1910 of 13,361,950 ac., but an increase of 7,784,590 ac. in improved land. By 1910 much of this land had been bought by speculators for sale in small farms and the land was in their hands or in those of purchasers who had not yet begun cultivation, and so was not included under farm acreage.

The value of all farm property in 1910 was \$2,218,645,164. Advance figures for the 1920 census, subject to correction, gave Texas 435,666 farms. The principal crops for 1920, in the order of acreage (according to estimates of the U.S. Department of Agriculture), were cotton, corn, oats, grain sorghums, wheat, hay, rice, peanuts, sweet potatoes, cowpeas, potatoes, broom corn, barley, sorghum syrup, rye. These crops covered 25,435,000 acres. Their farm value, partly estimated, was \$610,787,000. In 1919, at the peak of post-war prices, their value was \$1,051,817,000. Texas is a large producer of fruits and vegetables. Ranked according to value of the 22 principal crops produced in the United States, Texas held first place in 1919 and 1920; and first in the value of all crops 1914-20. The average annual yield of corn 1911-9 was 126,600,000 bus.; of wheat 15,300,000 bus.; of cotton 3,600,000 bales. Figures (partly estimates) of the U.S. Department of Agriculture gave Texas Jan. 1 1921 4,500,000 range cattle and 1,184,000 milch cows of the combined value of \$213,184,000; horses 1,187,000, valued at \$89,000,000; mules just under 800,000, valued at \$84,744,000; sheep 3,000,000, \$19,335,000, and swine 2,427,000, \$28,639,000. In the total value of live stock in 1920 Texas ranked second, between Iowa and Illinois.

Minerals.—The most important mineral products are oil, sulphur, coal and lignite. The first oil in paying quantities was discovered at Corsicana in the central part of the state, in 1894; but keen interest was not aroused until the "Spindle Top" discovery near Beaumont in 1901. Since that time the surface of the state has been covered with leases, and remarkable strikes have been made in a number of places. At the beginning of 1921 production was confined to two general sections—the coast, including mainly Harris and Brazoria counties (Jefferson, Hardin, and Matagorda counties have in the past been good producers); and a region in the northern and north-central part of the state, including chiefly Wichita, Eastland, Comanche, and Stephens counties. The Humble field in Harris county was opened in 1905, Goose Creek in 1911, and Blue Ridge in 1919. The west Columbia field in Brazoria county was also opened in 1919. The Burkburnett field in Wichita county first became important in 1917, Ranger in Eastland county in 1917, and Desdemona and Breckenridge in Comanche and Stephens counties respectively in 1918. Production dropped from 28,000,000 bar in 1904 to less than 9,000,000 in 1910; rose to 27,644,000 in 1916, 32,413,000 in 1917; 38,730,000 in 1918; 85,312,000 in 1919; and 54,668,000 for the first three-quarters of 1920. Natural gas and natural-gas gasoline were developed as by-products of the oil industry. The value of natural gas marketed in the state rose from \$127,000 in 1909 to \$5,027,449 in 1918; and natural-gas gasoline in 1918 amounted to 7,326,122 gal., giving Texas fifth rank in that respect. Two sulphur plants in Texas and one in Louisiana were said in 1920 to yield 98% of all that produced by the United States. One of the Texas plants is at Freeport, near the mouth of the Brazos river, the other is near Matagorda, close to the mouth of the Colorado. The Freeport plant began producing in substantial quantities in 1916, and the next year, under war pressure, delivered 500,000 tons. The Matagorda plant began operation in 1919, producing about 500,000 tons a year. The sulphur lies about 1,000 ft below the surface and is extracted from wells by "forcing superheated water (and steam) through pipes, dissolving and suspending the sulphur and pumping it back." Bituminous coal production from 1908 to 1918 remained practically stationary, varying from 1,010,000 tons in 1910 to 1,259,000 tons (value \$3,140,253) in 1917. The yield in 1919 dropped to 793,000 tons. Lignite is mined principally for state consumption, and the relative backwardness of manufacturing and the competition of other fields keep down the demand. More than 1,000,000 tons were delivered in each of the years 1913-5 and 1917-8. The 1919 yield was 860,000 tons. The value at the mine was slightly under \$1 per ton. The original supply was estimated in 1913 at 30,000,000,000 tons, of which about 9,000,000 tons had then been mined. Other minerals of fairly steady yield are silver, worth about \$500,000 a year for many years, quicksilver, cement, and clay products. In quicksilver production the Terlingua mine in Brewster county has for more than a decade made Texas second to California only. The highest yield recorded was 10,791 75-lb. flasks in 1917, valued at \$1,136,502. Cement production in 1919 was 2,288,000 bar., value \$4,176,000; clay products (brick, tile, and pottery) in 1917 were valued at \$3,451,806. Salt is produced in fairly steady quantities, and in 1917 yielded 85,181 short tons, with a value of \$564,000.

Manufactures.—In 1914 there were 5,084 manufacturing establishments, capitalized at \$283,544,000, employing 91,114 persons, and producing an annual value of \$361,279,000, of which \$108,135,000 was value added by manufacture. The principal industries were those concerned with lumber and timber, cotton-seed products, printing and publishing, oil-refining and allied products, flour and grist milling, and food preparations. The lumber production was 1,350,000,000 ft for 1918, when Texas ranked sixth in this industry, as it had done in 1910 and 1915.

Commerce.—The noteworthy ports are Sabine, Port Arthur, Orange, and Beaumont in the Sabine district, importing chiefly crude oil, and exporting refined oil and oil products; and Houston, Texas City, Freeport, and Galveston in the Galveston district, which export cotton, grain and sulphur. Houston is a new port, opened in

1915 Its access to the Gulf of Mexico is through the Houston Ship Channel, formed, for the most part, by the widening and deepening of Buffalo bayou. At the beginning of 1921 the controlling depth of the channel was 25 ft. and the width at bottom varied from 110 to 260 feet. The distance from the municipal docks to the Gulf is 54 miles. Unofficial but reasonably dependable figures for 1920 fixed the value of imports through Galveston, including the subsidiary ports of the district, at \$30,964,285, and the exports at \$627,498,478, making Galveston second to New York as an exporting port, a position which it had held for some years. These figures did not include coastwise traffic. During the year 1,233 vessels cleared for foreign ports, of which 849 were American, 222 British, 29 Norwegian, 26 Italian and 18 Mexican. The bulk of their cargoes was made up of 2,126,717 bales of cotton and 44,726,000 bus. of wheat. Through the coöperation of Galveston county and the Federal Government the Galveston sea-wall was extended and completed in 1920 to a length of 6.3 miles. The total cost of the wall (see 11 430) was \$4,725,000. The concrete causeway connecting the island with the mainland, 10,642 ft. long, was nearing completion in 1921. The cost was to be \$3,750,000, and was to be borne by the county and the railways entering the city. The county and city of Galveston were permitted by state Acts of 1901 and 1903 to apply their state taxes for 17 years to storm defence improvements. In 1917 the privilege was extended for 10 years; and subsequently the same authority was granted to several other maritime counties.

Finance.—The value of all property assessed for state taxation on Aug. 31 1919 was \$3,012,819,287. The ratio of assessed value to real value varied from 66½% in some cities to 25% in some rural districts. Total receipts of the state treasury for the year were \$28,410,724, and total expenditures \$27,200,978. On Dec. 29 1920 there were 1,031 state banks, with capital, surplus and undivided profits of \$71,768,997. They had individual deposits subject to check of \$226,282,045, and time and savings deposits of \$35,380,482. On Nov. 15 1920 there were 561 national banks with capital, surplus and undivided profits of \$124,633,000, deposits subject to check of \$447,898,000; and time and savings deposits of \$60,374,000. Of the state banks 176 were members of the Federal Reserve system at the beginning of 1921.

Education.—For 1920 the school pop. (7 to 18 years of age) was 1,271,157; and the number of teachers employed in the public schools was 30,158, of whom 3,515 were negroes. The public schools are maintained by the income from the permanent school fund, by state and local taxes, and by legislative appropriations. The permanent fund consists of lands and interest-bearing notes derived originally from the sale of public lands. In Aug. 1920 it was slightly less than \$74,000,000. State taxes for school maintenance are a poll-tax, one-fourth the proceeds of the occupation taxes, and an *ad valorem* tax of 35 cents per \$100. The practice of making legislative appropriations to supplement the available school fund began in 1915 with \$1,000,000 to aid rural schools. The practice continued, and for the biennium 1919-21 \$6,000,000 came from this source for general maintenance. A constitutional amendment adopted in Nov. 1920 removed the limit of 50 cents per \$100 which rural districts and unincorporated towns might appropriate for schools. The total available state fund for the year ending Aug. 1921 was \$18,564,507, to which should be added nearly \$13,000,000 from local taxes. A compulsory attendance law became effective in 1918, requiring, with specified exceptions, the attendance of children between 8 and 14 for at least 100 days each year. The following year a free textbook law went into effect. A law of April 3 1918 requires all public-school work to be conducted in the English language, but does not preclude the teaching of foreign languages.

Administration.—The attorney-general, comptroller, treasurer, and secretary of state head constitutional departments, and all are elective except the last, who is appointed by the governor. The more important statutory departments, in the order of their establishment, are those of the adjutant-general, superintendent of public instruction, state health officer, life insurance and banking commissioner, commissioner of agriculture, Railroad Commission, Live-stock Sanitary Commission, Fire Insurance Commission, the Industrial Accidents Board, the Board of Water Engineers, the Highway Commission, and the Board of Control. All are appointive directly or indirectly by the governor (with approval of the Senate), except the superintendent of public instruction, the commissioner of agriculture, and the Railroad Commission. Their terms vary from two to six years. The Industrial Accidents Board was created in 1913, primarily to administer the Employers' Liability Act. It consists of three members, one of whom must be a wage-earner, one an employer in some industry covered by the Act, and the third a practising attorney. The Board of Water Engineers was created in 1913 to regulate the use of public water for irrigation and all other purposes. The Highway Commission, established in 1917, consists of three members, and is charged with the administration of all highway laws, including that for the registration of motor vehicles. At the close of 1920 there had been completed under its supervision 976 m. of approved highways, costing \$5,326,000, of which \$1,308,000 was from Federal and \$904,000 from state aid. The remainder was paid by the local counties. At the same time contracts were in progress for the construction of 2,039 m. of road at an estimated cost

of \$23,277,000, of which \$8,650,000 was to come from Federal and \$1,437,000 from state aid. Federal and state quotas are apportioned in a certain ratio to local expenditure. The Commission reported the registration during 1920 of 427,693 automobiles and trucks and 4,290 other motor vehicles. The state Board of Control, created in 1920, represents an effort to consolidate administration and to coordinate the state budget. It is composed of three members, holding office for six years, one retiring every two years. Its budgets are subject to review and amendment by the Legislature. Departments created during the decade 1910-20, but showing signs of instability, are those of markets and warehouses (including weights and measures) and an Industrial Welfare Commission, created in 1917 and 1919 respectively. The dwindling jurisdiction of the Railroad Commission, suffering from the encroachments of the Interstate Commerce Commission, was somewhat compensated by an Act of March 1919 placing pipe-lines and drilling regulations under its supervision, and another of June 1920 giving it authority over natural-gas production. The Commission reported in Dec. 1918 15,866 m. of railroad in operation, an increase of 1,922 m. since 1910.

History.—After about 1880 prohibition was perhaps the most bitterly contested issue in state politics. A constitutional amendment providing for state-wide prohibition was voted down in 1887 and again in 1911; but was carried in 1919. In the meantime prohibition by local option had made great progress, so that by 1918 more than three-fourths of the area of the state, including the cities of Dallas, Waco and Austin, was dry. The Legislature in March 1918 ratified the Federal amendment, and in April put into effect the "zone" law, prohibiting the sale of liquors within 10 m. of a military, naval, or shipbuilding establishment. In June 1918 statutory state-wide prohibition was established, and doubts of the constitutionality of the Act were ended by the amendment of the next year. The Dean law (July 1919) is one of the most drastic of enforcement Acts. A law of March 26 1918 permitted women to vote in party primaries and nominating conventions; but a constitutional amendment, submitted the next year, to enfranchise women in regular elections, failed. The Legislature nevertheless ratified the Federal Woman Suffrage amendment in July 1919. The effect of the World War is seen in a law of April 2 1918, confining the franchise in primary elections to citizens of the United States, and in another of March 23 1918, amended a year later, providing that assistance should be given at the polls only in the English language and to persons physically unable to write or to those past 60 years of age and unable to read. Aliens could not be debarred from voting in final elections without amendment of the constitution, but preponderance of the Democratic party makes the primary election, in effect, definitive.

The total registration in Texas under the Selective Service Act was 990,522. From the best figures available in July 1921, there were 13,191 voluntary enlistments in the regular army, and 18,573 in the National Guard (transferred to Federal Service in the summer of 1917), and 127,531 inductions (not including officers) under the draft law; while 13,599 men and 6 women served in the regular navy and 4,505 men and 107 women in the naval reserve. The total number in both services, not including all officers, was 177,512. The total losses (officers and men) were 2,722, of whom 1,164 were killed in action, 456 died of wounds, 942 of disease, and 160 from other causes. The wounded numbered 7,331. Figures for the Texan subscription to the First Liberty Loan were not separately available. The eleventh Federal Reserve district, in which the state is included, subscribed \$48,948,350. The Texan subscription to the four following loans was \$363,273,350. When the Armistice was signed the Emergency Fleet Corp. had wooden ships under construction at Beaumont, Orange and Rockport, and in the Houston Ship Channel. Contracts had been let for 97 hulls and for 18 barges, of which were completed 52 hulls with tonnage of 196,400; and 4 barges aggregating 9,000 tons.

The governors of Texas after 1910 were Oscar Branch Colquitt (Dem.) 1911-5; James E. Ferguson (Dem.) 1915-Sept. 1917; William P. Hobby (Dem.) 1917-21, and Pat M. Neff (Dem.) 1921-. Mr. Ferguson was removed from office by impeachment and was succeeded, *ex officio*, by Lt.-Gov. Hobby, who was subsequently elected for one term, 1919-21.

(E. C. BA.)

THAYER, ABBOTT HANDERSON (1849-1921), American painter and naturalist (see 26 728), died at Dublin, N.H., May 29 1921. During the World War he worked in England on the development of camouflage.

THAYER, WILLIAM ROSCOE (1859-), American writer, was born in Boston, Mass., Jan. 16 1859. He studied at St. Mark's Academy, Concord, N.H., travelled with a private tutor in Europe, and graduated from Harvard in 1881, in the class with Theodore Roosevelt. For several years he was assistant editor of the *Philadelphia Evening Bulletin*, then returned to Harvard, receiving the degree of A.M. in 1886. When the *Harvard Graduates' Magazine* was established in 1892 he was appointed editor, serving until 1915. In 1903, at the International Historical Congress at Rome, he represented both Harvard University and the American Historical Association, and in 1906 was their representative at the Italian Historical Congress in Milan. He was a member of the Harvard Board of Overseers from 1913 to 1919. In 1902 he was made Knight of the Order of the Crown of Italy, and in 1917 Knight of the Order of Saints Maurizio and Lazaro. In 1918 he was elected president of the American Historical Association. He was best known for his works on Italian history, especially *The Dawn of Italian Independence 1814 to 1840*, 2 vols. (1893); *A Short History of Venice* (1905), and *The Life and Times of Cavour*, 2 vols. (1911). His other works include *Italica* (1908); *The Life and Letters of John Hay*, 2 vols. (1915); *Letters of John Holmes* (1917); *Theodore Roosevelt—An Intimate Biography* (1918); *Democracy: Discipline: Peace* (1919, lectures at Brown University); *Volley's From a Non-Combatant* (1919), and *The Art of Biography* (1920, lectures at the university of Virginia).

THEAL, GEORGE MCCALL (1837-1919), British historiographer, was born in Canada, where his family had long been settled. When 19 he went to Sierra Leone, removing two years later to Cape Colony, where he became a schoolmaster. He quickly developed an interest in the natives and in the history of the country. In 1877, on behalf of the Government he settled a dispute with the Gaika Kaffirs, and thereafter joined the Cape Civil Service, being attached to the Native Department. Shortly afterwards he was also appointed Keeper of the Archives, and in 1891 was made Colonial Historiographer, which position he held until 1905. Before joining the Civil Service he had published in one volume a *History of South Africa* and the first fruits of his Bantu studies were embodied in *Kaffir Folk Lore* (1882). From the time he obtained access to the Cape archives he devoted himself to research. In 1895 he was commissioned by Cecil Rhodes, then Prime Minister of Cape Colony, to go to Europe, where he stayed several years examining the Portuguese archives at Lisbon, the Dutch archives at The Hague and the British in London. He constantly enlarged and revised his *History* which in its final form was in eleven volumes, the first dealing with ethnography and conditions up to 1505, the others carrying on the story of S. Africa up to 1884. Theal also published official *Records of the Cape Colony, 1793-1827*, in 36 slim volumes, *Records of South East Africa* in nine volumes, and many other works, some in Dutch.

Theal's industry never flagged. He died at Wynberg, Cape Province, on April 17 1919, in the act of correcting the proofs of the last two volumes of his history. The founder of what may be called the Dominions school of historians, he was himself a chronicler rather than an historian. His passion for research brought to light a mass of unknown or forgotten documents of high value, but his narrative is overloaded with details, is essentially domestic, and not always impartial. He lacked the wider vision which sees events in their true perspective. Theal was given the honorary degree of Litt.D. by the Cape University in 1899, he had previously been made an hon. LL.D. of Queen's University, Kingston, Canada.

THERMIT, AND THERMIT WELDING.—Thermit is a mixture of aluminium powder and iron oxide. On ignition the reaction, $8\text{Al} + 3\text{Fe}_2\text{O}_3 = 9\text{Fe} + 4\text{Al}_2\text{O}_3$, gives a temperature estimated to be between $2,300^\circ$ and $2,700^\circ\text{C}$. The reaction, stated in weights, means that 217 parts of aluminium plus 732 parts magnetite

(iron oxide) equals 540 parts steel plus 409 parts slag, or approximately 3 parts of aluminium plus 10 parts of magnetite will produce, on combustion, 7 parts of steel. This steel represents about one-half of the original thermit by weight and one-third by volume.

Thermit was discovered by Dr. Hans Goldschmidt of Essen, Germany, in 1895, while trying to reduce chromium and manganese. Dr. Goldschmidt's principal discovery related to a simple and safe method of ignition, as the action of aluminium when mixed with various oxides, sulphides, and chlorides was well known. Fine aluminium will not burn below the temperature of molten cast iron, and previous experimenters had resorted to heating their mixtures in a crucible. This made the initial temperature so high at the moment of ignition that there was an explosion. Dr. Goldschmidt obtained ignition of a cold mixture by means of a barium-peroxide fuse, which was set off by a storm match. Later magnesium powder or ribbon was used, being set off in the same way. A red-hot iron rod may also be used to set off the magnesium, which in turn ignites the thermit. Dr. Goldschmidt's original American patent No. 615,700 was granted March 16 1897, and related principally to the use of aluminium as a reducing agent for the production of carbon-free metals such as cobalt, chromium, magnesium, tungsten, etc., by what is now known as the aluminothermic process.

Thermit is now used considerably in the foundry for purifying iron and steel in the ladle. For this purpose the thermit is placed in a can on the end of a rod and plunged to the bottom of the molten metal. The intense heat generated tends to liberate many impurities which are carried away in the slag. The principal and better-known use, however, is in welding.

THERMIT WELDING.—Two methods are employed, known as the plastic and the fusion. The first is used for welding pipe and the latter for solid or large sections. In the plastic method, in which the

FIG. 1.—Showing the action of Thermit when poured into a pipe welding mould.

thermit is used merely for heating purposes, the ends of two pieces of pipe are machined square and clamped in a cast-iron mould with the ends butted together. This mould is in two parts, so arranged that the pipe ends may be forced together when heated. The thermit is placed in an open-top crucible lined with magnesia-tar, and ignited. After the reaction takes place the slag rises to the top of the molten metal, and is first poured into the mould as shown at the

FIG. 2.—Tapping a crucible showing a partial sectional view.

left in fig. 1. This slag forms a protective coating on the pipe and on the inside of the mould, and keeps the thermit from melting or burning through. At the right the thermit is shown flowing into the

mould and forcing out the bulk of the slag, but leaving a coating as mentioned. When the pipe ends become plastic they are forced together, completing the weld. After cooling the mould is easily knocked off, since the slag coating prevents adhesion. To weld a pipe takes from $\frac{1}{2}$ to 1½ minutes.

In fusion welding on solid sections, in which the thermit mixture forms a casting holding the parts together, a special V-shaped magnesite-tar-lined crucible, open at the bottom, is used. The hole in the bottom is closed by a headed plug, covered with refractory sand, which may be pushed upward. This crucible is placed over the mould, as shown in fig. 2, the proper amount of thermit put in and ignited. After the reaction, which takes about 35 seconds, the plug in the bottom is pushed up and the molten thermit allowed to run into the mould. In this method great care is taken to keep the slag from contact with the surfaces to be welded, and consequently enough thermit must be used to fill the mould before the slag on top of the melted metal can enter.

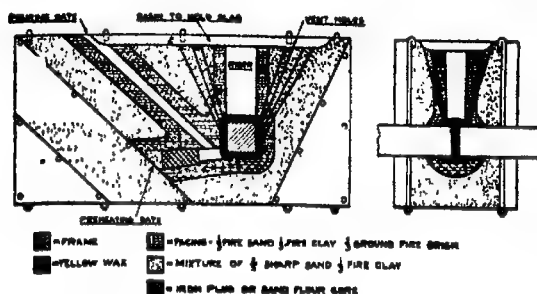

FIG. 3.—Sectional view of typical Thermit mould.

A typical mould for heavy sections is shown in fig. 3. In preparing to weld, the surfaces to be joined should be cut or set so as to be $\frac{1}{8}$ in. or more apart. Yellow wax is then built up around the joint in the same shape as the weld is to be. Next the mould box is placed and sand rammed up round the wax, wooden patterns being placed for the pouring gate, riser and preheating gate. The mould is vented, the patterns withdrawn, and a gas or oil flame used to melt out the wax. The heating is continued until the sections to be welded are red-hot. This prevents chilling of the thermit, which is poured in after the preheating gate has been plugged. The steps in making a typical thermit weld on a locomotive frame are graphically shown in

FIG. 4.—Steps in making a Thermit locomotive frame weld.

fig 4 Thermit welding is largely used in repairing broken rudder frames, propeller shafts, locomotive frames, steel rolling-mill pinions and other heavy sections, but it cannot be economically used for welding thin sheet metal sections. Welds have been made where from 3,000 to 4,000 lb. of thermit were used

For commercial purposes there are now produced three varieties of thermit, known as plain thermit, railroad thermit and cast-iron thermit. The plain thermit is simply a mixture of aluminum and iron oxide, as already given. Railroad thermit is plain thermit with the addition of $\frac{1}{2}$ % nickel, 1 % manganese and 15 % mild steel punchings. Cast-iron thermit is plain thermit with the addition of 3 % ferrosilicon and 20 % mild steel punchings. The names of these mixtures indicate their principal uses.

(E. Vi.)

THOMAS, AUGUSTUS (1850-), American playwright, was born in St. Louis, Mo., Jan. 8 1850. He was educated in the public schools, for several years worked in railway freight offices, and, after serving as special correspondent for various newspapers, became in 1880 editor and proprietor of the Kansas City (Mo.) *Mirror*. As a youth he had been a member of local amateur dramatic companies and had tried his hand at dramatic composition. One of these early pieces, *Edith's Burglar*, based on Mrs. Burnett's story of the same name, was enlarged to a four-act play and presented with great success at the Madison Square theatre in New York in 1880. This led him a little later to devote all his attention to the drama. His play *Alabama*

(1891), depicting the old-time South, contributed to the removal of sectional prejudice resulting from the Civil War. His numerous dramas include *In Mizoura* (1893); *The Hoosier Doctor* (1898, by many considered his best); *Oliver Goldsmith* (1900); *Soldiers of Fortune* (1902); *The Earl of Pawtucket* (1903, highly successful in England); *Mrs. Leffingwell's Boots* (1905), *De Lancey* (1905), *The Embassy Ball* (1905), *The Wutching Hour* (1909); *As a Man Thinks* (1912), *More Man* (1912), *Indian Summer* (1912).

THOMAS, JAMES HENRY (1878-), English Labour politician, was born at Newport (Mon.), of working-class parents, Oct. 3 1878, and was educated in the board schools. He started at nine years' old as an errand boy, but he soon passed into the service of the Great Western Railway Co., first as engine-cleaner, afterwards becoming fireman and engine-driver. He was elected town councillor of the famous Great Western railway centre, Swindon, and became chairman of the Finance Committee and of the Electricity and Tramways Committee. At an early date he associated himself with the development of the policy of unions among the railway servants. He became president of the A.S.R.S. in 1910, and for many years was secretary of the National Union of Railwaymen, and the most powerful voice in deciding their policy. He was elected to Parliament in the Labour interest for the great Midland railway centre, Derby, in 1910. For some years he took no very prominent part in Parliamentary life, being actively engaged outside in the interests of his railwaymen, who, besides many smaller disputes, came out in a body in the great strike of 1912. Another matter of vast importance in which he was deeply involved, was the organization of the so-called "Triple Alliance" between the unions representing coal-miners, transport workers, and railwaymen. When the war came, he took his stand, with the bulk of the Labour leaders, on the national and patriotic side; but, like many of them, deprecated the introduction of compulsory service, until it should be clear that the necessary men could be got in no other way. In Sept. 1915 he declared in Parliament that trade unionists were absolutely against conscription, that to introduce it might provoke revolution. Nearly every branch of his own railwaymen's organization, he said, had not only passed resolutions against the policy, but had threatened on its introduction to stop work. There were many who questioned at the time the justice of his estimate of the workmen's feelings; and, though he renewed his vehement protest against the first Military Service bill in Jan. 1916, and though the Labour party in conference condemned the measure, there was no difficulty in applying it and no agitation arose for its repeal. Even against the stronger measure of the following April only nine Labour members were found to go into the lobby on the second reading. Throughout the war Mr. Thomas, while securing large advances of wages for the railway servants, used his unique influence with them in composing disputes and preventing any stoppage which should interfere with national interests, and for this considerable service he was made a privy councillor in 1917. It was a bitter blow to him when in Sept. 1918 the rank and file disregarded an agreement which the executive of the National Union of Railwaymen had come to with the Government for an advance of 5s. for adults and 2s.6d. for boys. In spite of this, there was a general strike of railwaymen in S. Wales, and the disturbance spread partially to London and elsewhere, but the courts, on the application of the Board of Trade, prohibited the Union from paying strike pay, and the movement collapsed. In disgust at his advice being disregarded, Mr. Thomas resigned the secretaryship of the Union, but was eventually persuaded, on promises of better discipline, to resume office. He approved of the subsequent decision of the Labour party to sever itself from the Coalition, and to appeal to the electorate in Dec. 1918 for independent support, announcing as his own battle-cry "No more war." He was once more returned at the head of the poll for Derby, and by a huge majority. After the war he became a more prominent figure both in Parliament and in the national life. He made a strong speech in support of the Labour amendment to the Address in 1919, stating that he stood both against Bolsheviks and against profiteers. He called upon the Government to deal with

the reactionaries in Labour disputes as they would with Bolsheviks, and upon the employers to recognize that the working classes could no longer be treated by them as hewers of wood and drawers of water. He welcomed both the bill establishing a Ministry of Health and that establishing a Ministry of Transport; but he warned the House of Commons not to expect cheaper passenger fares and freight charges; the railwaymen would not allow themselves to be sweated for the benefit of the travelling public. But, once again, his real activity was outside. In the disputes in March 1910, between the railwaymen and the Government, he was the chief leader of the men, and at a moment of crisis he flew across to Paris to discuss the question with Mr. Lloyd George, then in attendance at the Peace Conference. The terms which he finally arranged with the Government, involving an approximate addition of over £10,000,000 per annum to the railway expenditure, included a standard week of 48 hours, and a standard wage for that week; for the fixing of the new standard rates of wages negotiations were to be continued. In the last week of Sept. he suddenly announced that a crisis had arisen in these negotiations, and after a futile conference with the Government on Sept. 25, a strike began without further notice on Sept. 26. Neither the community nor the Government was intimidated; and Mr. Thomas used his power for peace, and for a settlement, after ten days, on terms not materially different from what the men might have had at first. His efforts for the men had already, it was calculated, amounted to a permanent annual increase in the railway wage bill of £65,000,000, and an increase of 50%—which in Aug. 1920 became 75%—in passenger fares, and more than 50% in goods rates. In 1920 he and his executive were faced by the difficult problem of the refusal of Irish railwaymen to handle munitions of war; and the only solution he and they could suggest was that the Government should cease to send such munitions and that the Labour party should make an appeal to the Irish people—a solution which ministers, of course, could not accept. His own policy for Ireland was the gift of Dominion Home Rule. During this year he published a book *When Labour Rules*, in which he, speaking, of course, only for himself, depicted the kind of policy which Labour in power would favour—such as the right to work, development of nationalization, better homes, shorter hours, state endowment of motherhood, great extension of university facilities and a national theatre and opera.

THOMPSON, SILVANUS PHILLIPS (1851–1916), English physicist, was born at York June 19 1851, and educated at a school in Yorkshire belonging to the Society of Friends, of which body he was a lifelong member. He went later to the Royal School of Mines, having previously received a B.A. at London University when he was only eighteen. He obtained a B.Sc. from London University in 1875 with high honours and a D.Sc. in 1878, when he became professor of experimental physics in University College, Bristol. There he began his lectures on electrical science which brought him invitations to lecture all over the United Kingdom and made him a power in both the scientific and industrial worlds. In 1881 appeared his *Elementary Lessons in Electricity and Magnetism*, twice reprinted in 1882 and 16 times in the ensuing 12 years. A new edition was called for even as late as 1914. Two other courses of lectures were published in volume form, *Dynamo-Electric Machinery* (1882), and *The Electro-magnet and Electromagnetic Mechanism* (1891). By that time he had removed to London, becoming professor of Physics in the City and Guilds of London Technical College, Finsbury, in 1885 and subsequently its principal. He was elected a fellow of the Royal Society in 1889. In his desire to bring science home to the imperfectly educated he published anonymously *Calculus made Easy* by "F.R.S." (1910), written in colloquial style. His deep interest in religion, which led to his recognition in 1903 as a minister of the Society of Friends, inspired *The Quest of Truth* (1915) and a posthumous work *A Not Impossible Religion* (1918). He also published biographies of Reiss, Faraday and Kelvin. He died in London June 12 1916.

See *Silvanus Phillips Thompson, D.Sc., LL.D., F.R.S.*, by his wife and daughter (1920).

THOMSON, SIR JOSEPH JOHN (1856–), British physicist, was born near Manchester Dec. 18 1856 and was educated at Owens College, Manchester, and subsequently at Trinity College, Cambridge, where in 1880 he graduated as second wrangler. In the same year he was elected a fellow of Trinity College, and became second Smith's prizeman. In 1883 he was appointed lecturer in Trinity College, and in the following year Cavendish professor of experimental physics in the university of Cambridge, a position he occupied until his resignation in 1918. He developed a great research laboratory of experimental physics, attracting numerous workers from many countries and colonies; advances were made in the investigation of the conduction of electricity through gases, in the determination of the charge and mass of the electron and in the development of analysis by means of positive rays. He was elected a fellow of the Royal Society in 1884, became president of the Cambridge Philosophical Society in 1894, president of Section A of the British Association in 1896, and president of the Royal Society in 1915. In 1905 he held the professorship of physics in the Royal Institution, London, in addition to his Cambridge professorship. He was knighted in 1908 and awarded the O.M. in 1912. He was the recipient of many British and foreign awards and honours, amongst these being the Royal and Hughes medals of the Royal Society in 1894 and 1902 respectively, the Hodgkins medal of the Smithsonian Institute of Washington in 1902, the Nobel Prize for physics in 1906, enrolment as honorary graduate of many universities, and as honorary fellow of numerous American and continental scientific academies. During the World War he presided over several research committees and he assisted various Government departments in an advisory capacity. In 1918 he was appointed master of Trinity College, Cambridge, and in the following year was elected to a newly established professorship of physics in the Cavendish Laboratory, where he continued to prosecute his researches. In addition to a large number of publications in the *Proceedings of the Royal Society* and the *Philosophical Magazine*, he has published *A Treatise on the Motion of Vortex Rings* (1884); *The Application of Dynamics to Physics and Chemistry* (1886); *Recent Researches in Electricity and Magnetism* (1892); *Elements of the Mathematical Theory of Electricity and Magnetism* (1895, 5th ed. 1921); *The Discharge of Electricity through Gases* (1897); *The Conduction of Electricity through Gases* (1903); and, with Prof. Poynting, a number of text-books upon physics.

THORNE, WILL (1857–), British Labour politician, was born at Birmingham Oct. 8 1857. He started work at the age of seven in a ropeworks, attending the wheel of a rope-spinner for ten hours a day, and on Saturday afternoons and Sunday mornings toiled in a barber's shop. He afterwards became a gas-worker, and in 1889 he helped to found the National Union of Gas Workers and General Labourers, becoming its general secretary. This union (under the title of the National Union of General Workers) had in 1921 a membership of over 600,000. He became a member of the parliamentary committee of the Trades Union Congress in 1894. He was chairman of the Congress in 1912. In 1900 he contested West Ham unsuccessfully in the Labour interest, but in 1906 was elected to Parliament and came to the front as an active and energetic member of his party. At the general election of 1918 he was returned with a majority of 11,505. From 1890 he was a member of the West Ham town council, being elected mayor in 1917. He had been a member of the Social Democratic Federation since 1883.

THORNYCROFT, SIR WILLIAM HAMO (1850–), English sculptor (see 26 881), was knighted in 1917. His more recent works include the King Edward memorial at Karachi (1915) and "The Kiss" (1916), now at the Tate Gallery.

THÓRODDSEN, PORVALDR (1855–), Icelandic geographer, was born on the isl. of Flatey, in Breidvíðr, Iceland, June 6 1855, the son of Jón Thóroddsen (see 26 881), the poet and novelist. His father's death in 1868 left the family in poor circumstances, but the boy went to school at Reykjavík and in 1875 to the university of Copenhagen, where he studied natural science and geography. In 1876 he was sent to Iceland by the

Danish Government with Prof. Johnstrup to investigate the causes of the eruption which had occurred the previous year at Askja in Dyngjufjöll, and this proved the beginning of a long series of Icelandic explorations. In 1880 he was appointed master at the school of Möðruvellir in northern Iceland, and in 1882, 1883 and 1884 made extensive explorations in the interior. From 1884-6 he travelled in England and on the Continent, and in 1886 was appointed master of the school at Reykjavik. Until 1898 he made a journey of exploration nearly every year, the later expeditions being undertaken from Copenhagen, where he settled in 1895. Reports on his work appeared from time to time in the Danish *Geografisk Tidsskrift*, but he also produced various important works, including *Oversigt over de islandske Vulkaners Historie* (1882); *Vulcane im nordöstlichen Island* (1891) and *Landfræðissaga Islands* (1892), a monumental work for which he collected material from the beginning of his career. Thóróddsen received many honours from universities and learned societies, and was awarded the gold medal of the Swedish and the La Roquette medal of the Paris Geographical Society.

THURINGIA (see 26.901), a Territory and Free State of the German Reich. Pop. 1,508,025. Area 11,763 sq. kilometres.

On April 30 1920 the union of the Territories Saxe-Weimar-Eisenach, Saxe-Meiningen, Saxe-Altenburg, Saxe-Gotha, Reuss, Schwarzburg-Rudolstadt and Schwarzburg-Sondershausen, in one Territory "Thuringia," was recognized by a law of the German Reich, on the basis of article 18, section 2, of the Constitution of the Reich. The consequence was thereby drawn from the abolition of the dynasties, whose policy of dynastic interests had in former centuries caused the disintegration of central Germany into small states. The removal of these dynasties had been effected in the Thuringian States, as in the Empire in Nov. 1918, by the method of revolution. A noteworthy exception was Schwarzburg-Rudolstadt, where the republic was established by a law enacted conjointly by the sovereign (the Prince of Schwarzburg-Rudolstadt) and the Diet.

The unification of the Thuringian States in one single State was preceded by the union of the two principalities of Reuss into one democratic State of Reuss. On the other hand the personal union of the two States of Coburg and Gotha was dissolved, and each of them went its own way. In all the States of Thuringia elections were instituted after the revolution by the revolutionary Governments for Constituent Assemblies to vote new constitutions. Only in Gotha was the meeting of the new State Assembly delayed. The Council of Workmen and Soldiers in that Territory was subject to Communist influence and endeavoured to establish a Councils (Soviet) Republic. Gotha had to be occupied in Feb. 1919 by detachments of the *Reichswehr* (regular army of the Reich). The workmen replied by a general strike which lasted more than a month. When the Assembly met, the Government of Gotha, which was composed of Independent Socialists, submitted the draft of a constitution which attempted to maintain the system of Councils (Soviets). The work of framing constitutions in all the Thuringian States had meanwhile been anticipated by the movement for forming a unified single State of Thuringia.

Steps in the direction of a union had been taken in some of the States of Thuringia before the revolution, but it was only by the revolution that the path was cleared. All the Thuringian States, with the exception of Saxe-Meiningen and Saxe-Coburg, concluded a "treaty of community" (*Gemeinschaftsvertrag*) in order to prepare for their amalgamation. They formed a kind of federated state with an organ of legislation, the *Volksrat* (Council of the People), and an organ of administration, the *Staatsrat* (State Council). Saxe-Meiningen subsequently joined this Community of States, in Saxe-Coburg a great majority of the citizens decided on Nov. 30 1919 for union with Bavaria, which was ratified by a law of the Reich on April 30 1920 on the basis of article 20 of the Constitution.

The *Volksrat* of Thuringia passed a law on Jan. 28 1920, by which it assumed the right to include within its competence the enactment of a constitution for the State of Thuringia. Nevertheless, there was to be reserved for the first Diet (*Landtag*) of

the new State, which was to be elected on the basis of this constitution, the right of making alterations in the constitution within a period of three months by ordinary legislation. On May 12 1920 the provisional constitution voted by the *Volksrat* (Council of the People) was promulgated. On March 11 1921 the newly elected Diet (*Landtag*) ratified this provisional constitution with certain amendments. The birth of the new State dates from May 1 1920, the day on which its establishment was voted by a law of the Reich. While the Thuringian Community of States (see above) was organized on the lines of a confederation, what was in contemplation is a single, unified State. For the period of transition, however, the separate Thuringian States continued to exist as communities or territorial regions (*Gebiete*); their former constitutions remained in force as regional regulations (*Gebietssatzungen*). If any disputes should arise between the Territory of Thuringia and the former Thuringian States, the Court of Jurisdiction for State affairs (*Staatsgerichtshof*) was to decide them, for the settlement of financial differences a court of arbitration, half of whose members were to be elected by the Thuringian Diet and half by the popular representative assemblies of the former States concerned, was to be set up.

In accordance with the Constitution of the Reich, Thuringia is a republic with parliamentary government. The Diet, as in the other Territories, consists of a single Chamber elected on a system of proportional representation. It can be dissolved by a popular vote (*Volksentscheid*). The peculiarity of the Thuringian Constitution is that the committees of the Diet may call in experts to supplement their membership. The executive power is in the hands of the Ministry, which is formed on the principle of equal colleagues (*Kollegialprinzip*) and consists partly of members who hold office and partly of members who hold no office and who are designated State Councillors (*Staatsräte*). The members of the Ministry are appointed by the Diet. The president of the Ministry is chosen by the Ministry and is merely its chairman. The Thuringian constitution does not provide for any President of the State. The legislative prerogatives of the Diet are limited, as in the other German Territories, by the right of the people themselves to vote laws; the people can be invited to give their vote (referendum) upon a law which has already been passed and may likewise by their own initiative cause the expression, in a vote, of their will (*Volksbegehren*).

(W. v. B.)

THURSTON, ERNEST TEMPLE (1879-), English novelist, was born at Halesworth, Suffolk, Sept. 23 1879. At the age of 16 he published two volumes of verse. Two years later he published his first novel, *The Apple of Eden* (1897, republished 1905), followed by *Traffic* (1906); *The Evolution of Katherine* (1907); *The Realist* (1907); and two widely differing but very successful novels, *Sally Bishop* (1908) and *The City of Beautiful Nonsense* (1909). His later work includes, on the realistic side, *The Antagonists* (1912) and *Richard Furlong* (1913), and on the sentimental side *The Greatest Wish in the World* (1910); *The Garden of Resurrection* (1911); *Enchantment* (1917) and *The World of Wonderful Reality* (1920). He dramatized his wife's novel, *John Chilcote, M.P.* and one or two of his own, and wrote also, as original plays, *Driven* and *The Cost* (1914), and *The Wandering Jew* (1920).

His wife, KATHERINE CECIL THURSTON (d. 1911), was born at Cork, the daughter of Mr. Paul Madden. She married Mr. Thurston in 1901, but in 1910 her marriage was dissolved on her own petition. She was well known as a writer of novels, notably *The Circle* (1903), *John Chilcote, M.P.* (1904); *The Gambler* (1906) and *The Fly on the Wheel* (1908). The second of these, a study of dual personality, created a considerable stir, both as a novel and as a play. She died at Cork Sept. 6 1911.

TIBET (see 26.916).—In Feb. 1910, at the approach of a small Chinese force, which had invaded Tibet under Gen. Chun Ling from Szechuen, the Dalai Lama fled to India and was deposed by imperial decree. In exile at Darjeeling, he appealed for British intervention at Peking, but the British Government declined to dispute the authority of the *de facto* Government in Tibet. At the same time, H.M. Government took occasion to draw the attention of the Government at Peking to the necessity

for strict adherence to the terms of the treaty concluded in April 1906, and particularly to the inviolability of the frontiers of Nepal, Bhutan and Sikkim. The last two years of the Manchu dynasty witnessed the restoration of China's effective suzerainty in Tibet from the border marshes to Lhasa, a result chiefly due to the energetic and capable administration directed by Chao Erh-feng, viceroy of Szechuen.

But the province of Szechuen was among the first to be reduced to anarchy by the upheaval of the revolution of 1911, and after the assassination of Chao Erh-feng, the authority of China as suzerain power in Tibet was speedily challenged and overthrown. When the news of the revolution reached Lhasa, the Chinese garrison hastened to throw off its allegiance and following the example of the troops in China, indulged in lawlessness and looting at the expense of the civil population. The latter, led by the ever-restless lamas, took up arms against the invaders and the Chinese garrison found itself cut off from its base and besieged. Desultory fighting continued until the return of the Dalai Lama from India; peace was then (Aug. 1912) locally concluded, under an agreement by which all Chinese troops (with the exception of the Chinese resident's body guard) evacuated the country, departing via India after depositing their arms at Lhasa. By this time China's garrisons had been expelled and her authority overthrown in eastern Tibet by the semi-independent chieftains of that region. The Government of the republic at Peking, desiring to recover the prestige thus lost, authorized the despatch of a punitive expedition, consisting of forces raised by the military governors of Szechuen and Yunnan. The expedition started from Chengtu in July 1912; it had reached and captured Batang in Aug., when, as the result of representations made by Great Britain at Peking (Aug. 19), its advance was stopped and the project subsequently abandoned.

The British Government, in requesting China to abstain from these military operations in Tibet, took the ground that such action constituted a violation of the treaty of 1906. While China's suzerainty was not disputed, the Government could not consent to the forcible assertion of full sovereignty over a State which had established independent treaty relations with Great Britain. The Chinese Government was therefore invited to negotiate a new tripartite agreement defining the status of Tibet. To this communication China replied on Dec. 23; meanwhile the expedition had been countermanded, but desultory fighting continued between Szechuen troops and the Tibetans of the border marshes. The Chinese Government's reply justified its military operations, on the ground that the Tibetan trade regulations of 1906 gave them the right to police the trade marts and protect lines of communication. The republic, it declared, had restored the Dalai Lama to his former position and titles and had no intention of making Tibet a Chinese province, but would scrupulously respect the traditional system of Tibetan Government. Reference was made to the Indian Government's unfriendly act in preventing communication between China and Tibet, via India, and the hope was expressed that this policy might be reconsidered; but the Chinese Government saw no reason for negotiating a new treaty. Before the end of the year, the last of the Chinese forces had been driven out of Tibet, and on Jan. 11 1913 the Dalai Lama proclaimed the independence of the country by concluding a treaty with the Living Buddha (Hutukhtu) of Urga (Outer Mongolia). In April, hostilities were resumed by the military governor of Szechuen; at the same time negotiations with the Dalai Lama were opened by President Yuan Shih-k'ai, who sent a delegate to Chamdo to discuss terms of peace. In May the British Government renewed its proposal for a tripartite conference, which was ultimately accepted. The conference opened at Simla on Oct. 13; Great Britain was represented by Lt.-Col. Sir A. H. McMahon, China by Mr. Ivan Chen, and Tibet by her prime minister, Long Chen Shatra.

China's position at this conference was generally negative; while promising not to convert Tibet into a Chinese province, the Peking Government asked that Great Britain should respect China's position as suzerain and undertake not to annex any portion of the country. Great Britain proposed the creation of an

Inner and an Outer Tibet, the former to enjoy autonomy, the latter under Chinese control. The Tibetan representative asked for complete independence and frontier rectifications. The result of the subsequent negotiations, which continued till July 1914, was a draft treaty, which the Chinese Government declined to ratify. It provided for Tibetan autonomy and recognized China's position as suzerain power, while limiting the representation of that power to a Resident with a suitable guard at Lhasa. It differentiated between the complete autonomy of Inner and the semi-autonomy of Outer Tibet. China's refusal to ratify this treaty was not due to any definite objection to its specific conditions, but to her unwillingness to accept the geographical definition of the frontiers of Outer Tibet, as proposed at Simla.

After the break-up of the conference, the Chinese Government agreed to the suspension of all hostilities against Tibet pending a renewal of negotiations, and for the next three years a state of armed vigilance was maintained on the Szechuen border. In July 1917, however, a fresh cause of strife occurred in the arrest of two Tibetans by Chinese troops near Chamdo. The Kalong Lama's request for negotiations on the subject was refused, and the armistice was broken by the Chinese general commanding in the marshes, without reference to Peking. In the fighting which ensued, the Tibetans proved victorious; by Feb. 1918 the Chinese garrison at Chamdo was surrounded, and the whole country to the eastward, as far as the right bank of the Yangtse, in the hands of the Tibetans. Chamdo surrendered in April, and the Chinese proposed to negotiate for peace. In July an armistice was arranged, at the instance of Mr. Teichman, the British vice-consul, this was followed by a peace conference at Chamdo, at which it was agreed to suspend hostilities for a year, the Tibetans retiring within the boundary of Derge and the Chinese to Kansue. In Sept. 1919 the Chinese Government at Peking proposed a renewal of the negotiations abandoned at Simla in 1914 and gave evidence of its desire to put an end to hostilities, on the Tibetan side there were also indications of a desire for peace. The situation, however, was (and remained) complicated and difficult by reason of the fact that the authority of the Peking Government was ignored by the usurping provincial satraps of Yunnan and Szechuen, and also because the delimitations of any permanently satisfactory frontier for Outer Tibet presented serious problems, ethnological as well as strategic and political.

See *Blue Book on Anglo-Tibetan Relations* (1910); Sven Hedin, *Trans-Himalaya* (1913); Reginald Farrer, *On the Eaves of the World* (1917); *The China Year Book* (1919). (J. O. P. H.)

TIDES (see 26.938).—The present century has seen a marked increase in the interest taken among foreign scientists in the study of the tides, while in Great Britain the subject again received much attention after the close of the World War.

Observation—The automatic tide gauges which are distributed along the coasts (in Great Britain very irregularly and chiefly according to the needs or caprices of harbour authorities) require much more attention than it has been the custom to pay to them. The errors in both elevation and time of their elevation-time graphs should be determined by independent observation at least once a day, as such errors very easily attain serious dimensions.

But the outstanding scientific need of the present time is for off-shore observations. Not only do the great tidal movements of the ocean remain practically unobserved, but in the middle of the Irish Sea, for example, there is a discrepancy of 40 m. between the cotidal lines of different authoritative charts.

Off-shore elevations have been recorded by personal soundings (at the Dutch lightships, for example) but a number of attempts have been made to construct a self-registering gauge which, when placed on the bottom of the sea, will give a continuous pressure-time record. From such a record it is of course easy to pass to an elevation-time relation. Up to 1921 the gauge which appeared to have met with most success was that of M. Favé, of the French Marine, and even this had not worked in water of depth greater than 200 metres.

Continuous current observations are required at all depths. A knowledge of currents is of immense importance both commercially and scientifically, and the effect of currents on mines during the World War caused much attention to be paid to them by naval authorities. Tidal currents are oscillatory, but observed currents have, as a rule, a residual drift which is of particular importance in general oceanographical or fishery research.

Surface currents have been measured by floating logs (as for most of the data published by the British Admiralty) but series of ob-

servations at frequent intervals, especially of currents below the surface, are usually made by current meters. One of the commonest of these—the Ekman meter—registers the mean speed and direction of the current during the interval of time it is in operation, the former by a small propeller actuating a revolution counting apparatus and the latter by a vane attached to an apparatus dropping shot into sectorial boxes on a compass card. It has thus to be hauled up to the surface for each reading. Continuous recording instruments are much needed and though some have been invented they do not appear to have been much used. Owing chiefly to the trouble of keeping a meter fixed relatively to the bottom, the accurate measurement of currents is a matter of great difficulty. Other data for residual currents or drifts are given by observations of weighted bottles or other forms of floating bodies, or by instruments so contrived as to float near the sea bottom.

General Distribution of Off-shore Tides.—Much attention is now paid to the "amphidromic points," at which there is no rise and fall of the water and out from which the co-tidal lines radiate. Harris' charts of co-tidal lines contain a number of these points and so does the new chart of R. Steinbeck (*Sitzb. d. Akad. Wissensch., Wien*, 129, 1920), which is based on all available data.

All recent charts of co-tidal lines for the North Sea agree in placing an amphidromic point in the southern region, and one of the services of the Favé gauge has been to give fresh observational verification of its existence (*Comptes Rendus*, 151, p. 803, 1910).

Dynamical Theory of the Tides.—As regards the tidal dynamics of completely defined bodies of water, the only basins which had yielded to mathematical treatment up to 1914 were those of a flat circular sea, the depth of which was a function only of the distance from the centre, and an ocean covering the whole globe with the depth a function only of the latitude. The details for zonal basins of uniform depth have since been worked out by G. R. Goldsbrough (*Proc. London Math. Soc.*, 14, 1914; 15, 1915).

Two attempts have been made, however, to bring some of the latest results of pure mathematics to bear on the general problem. In 1910 Poincaré published his transformation of the dynamical equations from the differential to the integral form (*Leçons de Mécanique Céleste*, t. 3). The theory of integral equations has grown up almost entirely since 1900, its results are perfectly general and are stated explicitly in terms of direct operations. But in the case of tidal problems the arithmetical labour necessary to carry out these operations is so prodigious as to prove quite prohibitive even for the reproduction of known solutions. Nevertheless, the theory is valuable for the establishment of existences.

Utilizing these existence-theorems J. Proudman (*Proc. London Math. Soc.*, 18, 1917) has been able to specify the tidal state of an ocean by means of an infinite number of coordinates of the Lagrangian type, and then to transform the differential equations into an infinite set of linear algebraic equations. This has afforded a real prospect that the number of geometrically simple basins for which the tidal dynamics is completely known, may be increased.

The explanation, on dynamical principles, of the observed features of tides in small basins has been considerably advanced, chiefly by A. Defant and R. Steinbeck. See *Denkschr. d. Akad. Wissensch., Wien*, 96 (1919). *Sitzungsberichte*, 123 (1914), 124 (1915), 129 (1902). The method of treatment only applies to elongated bodies of water and applications have been made to the Red Sea, the Persian Gulf, the English Channel, the Irish Sea and the Adriatic Sea. The motion is assumed to consist of a longitudinal oscillation sustained chiefly by the tides outside, with a transverse surface gradient sustained by the longitudinal current through the earth's rotation.

Other parts of the dynamical theory which have undergone development are those relating to slowly rotating seas and oceans, limiting forms of long period tides and the diffraction of tidal waves. See Rayleigh, *Proc. Roy. Soc. (A)* 82 (1909), J. Proudman, *Proc. London Math. Soc.*, 12 (1913), 13 (1913), 14 (1914). In this connexion it may be mentioned that there is an erroneous statement in 26 957 §34, to the effect that the existence in the ocean of continental barriers would have the same effect as that attributed by Laplace to friction. In the actual oceans limiting forms of long period tides are possible which do not take the "equilibrium" values.

Harmonic Analysis.—From 1883 up to the present time the standard harmonic development of the generating potential has been that of G. H. Darwin. Quite recently A. T. Doodson has made a new development, working to a much higher order of approximation than Darwin, and has found that there is a very large number of other constituents which, while certainly being smaller than those of Darwin, are not very much smaller, and in their aggregate may be important. In other words, the convergence of the series of constituents is not so rapid as has been assumed.

A corresponding state of affairs exists with regard to *overtides and compound tides*. For certain British stations A. T. Doodson, being led by dynamical principles, has found it possible to obtain a practically complete representation of the quarter diurnal tides, but it involves many more harmonic constituents than have ever been sought for by the customary methods. This representation is susceptible of very simple algebraic statement and numerical application but cannot be used on the existing predicting machines.

The present state of analysis is not satisfactory. The harmonic constants do not represent completely the records analysed for

certain British stations the discrepancy may have a quarter-diurnal range of one foot and a semi-diurnal range of one foot.

J. Proudman (*British Assoc. Report*, 1920, p. 323) has given an account of British work on harmonic analysis with a bibliography and lists of analyses made.

Tide Tables cannot be regarded as satisfactory even for such practical purposes as docking large vessels or navigating over shallows, while for a hopeful study of meteorological effects they are almost useless. The main deficiency appears to be one of analysis of records; for others, see A. T. Doodson, *Brit. Assoc. Report*, 1920, p. 321.

When the astronomical tides can be predicted with the same degree of accuracy as the resultant tides can be observed, there appears to be no reason why short date predictions of meteorological tides—obviously of great importance—should not be attempted.

Atmospheric Pressure and Wind.—The effects of meteorological influences on the tides have been much studied, especially by the Scandinavians. As regards the relative importance of atmospheric pressure and wind, a general conclusion appears to be that at a station in the immediate neighbourhood of a wide expanse of deep ocean, the direct pressure effect predominates, whereas at a station in a landlocked and shallow sea, the wind effect predominates. The detailed study of these effects is rendered very difficult by the uncertainties in the predictions of astronomical tides, and most investigations have dealt with mean effects over long intervals of time. There is much literature on the subject: see for example D. la Cour, *Danske Meteorologiske Institut, Meddelelser*, 1 (1913), 4 (1917); R. Witting, *Fennia* 39, 5 (Helsingfors 1918). The 1917 memoir of la Cour is a detailed study of the effects of a storm.

Friction.—If tidal motion were everywhere non-turbulent then the amount of friction in the oceans would be quite insufficient to account for the outstanding discrepancy between theory and observation in the motion of the moon. See R. O. Street, *Proc. Roy. Soc. (A)* 93 (1917). But the motion associated with large tides in shallow seas is undoubtedly turbulent and though this has long been recognized it is only recently that numerical estimates of its amount have been made. See G. I. Taylor, *Phil. Trans. (A)*, 220 (1920), H. Jeffreys, *ibid* 221 (1920), concludes that the total amount of friction is just about sufficient to account for the discrepancy mentioned. He takes the chief contributing areas to be Herring Sea, the Yellow Sea, Malacca Strait and the American N.W. Passage.

History and Bibliography.—To the list of outstanding names in the history of the theory of the tides should be added those of G. H. Darwin and H. Lamb. The chief contributions of the former were his elaboration of the methods of harmonic analysis and his far-reaching cosmogonical deductions as to the consequences of tidal friction. The chief contribution of the latter is in connexion with steady motions and the discrimination of free oscillations in the general dynamical theory. Additions to the list of books on tides are R. A. Harris, *Manual of Tides* v. (1907); H. Poincaré, *Leçons de Mécanique Céleste*, t. 3 (1910) and O. Krümmel, *Handbuch der Ozeanographie*, B. 2, C. 3 (1911).

TIENTSIN, China (see 26 963).—After the Chinese revolution of 1911 the political and social importance of Tientsin considerably increased, inasmuch as it became an unofficial place of residence, and often of refuge, for high Chinese officials in times of trouble, and a neutral ground convenient for the conferences of the northern military governors. The number of Chinese residents in the Foreign Concessions steadily increased after 1912 and building operations continued unabated. The World War naturally led to a greatly increased demand in most branches of the port's export trade, so that, in spite of floods, famines and brigandage, business was very prosperous after 1915. Local industrial enterprise was stimulated by the curtailment of imports from Europe and a lack of shipping facilities. In 1919 it received a fresh impetus from the boycott of Japanese goods, with the result that many new factories were established for the manufacture of goods heretofore imported.

The city produces cotton yarn in steadily increasing quantities, seed and groundnut oils, canvas, leather, soap, candles and numerous articles for domestic consumption; its chief exports during the war were furs and skins, wool, bristles, strawbraid, carpets and prepared eggs. The value of the export trade in 1919 was 71 million taels, as against 51 millions in 1918, and 42 millions in 1917. Tientsin's prosperous growth was indicated by the opening of four new Chinese banks in 1919. The coal trade, from the Kailan Mines in Chihli and the Peking Syndicates in Honan, has greatly increased since the adoption of the system of Anglo-Chinese cooperative working.

In Sept. 1917 the Foreign Concessions and the trade of the port suffered severely from floods, which burst the banks of the Grand Canal and inundated all the plain surrounding the city. Before normal conditions could be restored in the British, French and Japanese Concessions, the municipal councils were compelled to surround them with dikes and pump out the water. This flood also produced a shoaling of the river bar at Taku, with results seriously prejudicial to the trade of the port. With a view to preventive and remedial

measures, a Joint Commission for the improvement of waterways in Chubli was formed in 1918, upon the recommendation of the Haiho Conservancy Board, under the presidency of Hsiung Hsi-ling, with the assistance of European engineers and experts, in addition to the local work of river conservancy, this Board is charged to report on ways and means for restoring the navigability of the Grand Canal between Tientsin and the Yellow river, which has been for many years impracticable at certain seasons.

The foreign garrisons (American, British, French, German, Japanese and Russian) stationed at and around Tientsin under the terms of the Peace Protocol of 1901, for the protection of railway communication between Peking and the sea, were considerably increased after the outbreak of the revolution in 1911. At the end of 1913 their combined forces at Tientsin amounted to 6,000 men; but in the autumn of 1914 most of those belonging to the belligerent Powers were withdrawn. In March 1917 the Chinese Government took over charge of the German Concession; on Aug. 14 the Austrians were similarly dispossessed. Since then, both Concessions have been administered in accordance with preexisting municipal regulations, by the Chinese authorities. (J. O. P. B.)

TILAK, BAL GANGADHAR (1856-1920), Indian nationalist leader and orientalist, was born July 23 1856, at Ratnagiri, where his father, a Chitpavan Brahman, was an educational officer. At the Deccan College, Poona, he graduated in arts with honours in 1876, and took the LL.B. degree in 1879. In the following year he took the lead in providing secondary and higher education in Poona under Indian direction by founding an English school and the famous Fergusson College. Tilak conducted law classes till 1890, by which time he had become the sole proprietor as well as the editor of the two weekly papers, the *Mahratta* (in English) and the *Kesari* ("Lion" in Marhatti) which he and his friends had founded in 1880. These were the chief printed media of his anti-Government propaganda; but he took every advantage of public activities, such as membership of the local municipality and the organizing of Shivaji and Ganapati celebrations, to work upon the prejudices and passions both of the masses and of the educated minority. Identifying himself with Brahmanical orthodoxy he bitterly opposed social reforms. His violent condemnation in 1897 of the plague prevention regulations was followed by the assassination of the local plague commissioner (Mr. Rand) and a young British officer driving with him at the time. Convicted of sedition, he was sentenced to 18 months' rigorous imprisonment, but he was released within a year under pledges of good behaviour. In prison he pursued the Vedic studies which had already given him a place in oriental scholarship. His elaborate paper on "The Orion, or Researches into the Antiquity of the Vedas," read at the International Congress of Orientalists, London 1892 (published at Poona, 1893), was followed in 1903 by his "Arctic Home in the Vedas"—expounding a theory of extremely remote Aryan origins which has failed to secure the acceptance of other scholars. Tilak was twice elected to the Bombay Legislature for triennial terms. Again indicted for sedition in June 1908, he was sentenced by a Parsi judge (Mr. Justice Davar) to six years' transportation, afterwards commuted on account of age and health to simple imprisonment at Mandalay. On release in 1914 he actively promoted the home-rule campaign, and at last succeeded, after the death in 1915 of G. K. Gokhale, in his prolonged struggle to secure for his party control of the Indian National Congress. A libel suit he instituted in London against Sir Valentine Chirol for statements made in *Indian Unrest* (1910) ended in a verdict for the defendant with costs (Feb. 21 1919). On returning to India he refrained from definite association with the non-cooperation cult. His death in Bombay, Aug. 1 1920, was followed by demonstrations of mourning throughout India, showing his remarkable hold on the popular mind.

Tilak's formative part in the cult of Indian unrest is shown in the *Report of the Rowlatt Sedition Committee*, 1918. His speeches are collected with an appreciation by Aurobinda Ghose in *Lokmanaya B. G. Tilak*, Madras, 2nd edition, 1920. (F. H. Br.)

TILLET, BENJAMIN (1860-), British Labour politician, was born at Bristol, Sept. 11 1860. He started work in a brick-yard at eight years and was a "Risley" boy for two years. At 12 years he served for six months on a fishing smack, was afterwards apprenticed to a bootmaker and then joined the Royal Navy. He was invalided out of the navy and made several

voyages in merchant ships. He then settled at the London Docks, and organized the Dockers' Union of which he became general secretary in June 1887, taking a prominent part in the dock strike of 1889. He was subsequently one of the pioneer organizers of the General Federation of Trades, National Transport Workers' Federation, National Federation of General Workers, International Transport Federation, and the Labour party. For many years he was an alderman on the L.C.C. After standing for Parliament unsuccessfully four times, he was elected in 1917 as Labour member for N. Salford. In 1920 he published *A Brief History of the Dockers' Union*, commemorating the 1889 dockers' strike, and in 1921 *A History of the London Transport Workers' Strike*.

TIME (see 26.983).—The progress of wireless telegraphy has greatly simplified accurate determination of Greenwich time and consequently of longitude.

Determination of Time—The chief difficulty in determining local time from observations of the altitudes of celestial objects is that of getting a satisfactory horizon. In the case of airships the view of the horizon is much interfered with by cloud, and the dip of the horizon is a more important and uncertain factor than in ordinary navigation at sea. When the airship R34 crossed the Atlantic in 1919 observations were made from a "cloud horizon" the height of which could not be known with accuracy. During the World War several sextants were designed in which the use of a pendulum or level enables the altitude of celestial objects to be determined without reference to the horizon, but they have not come into general use.

For the determination of Greenwich time at sea astronomical methods have been practically abandoned, and extreme accuracy in chronometers is no longer necessary. Signals are sent out daily at specific instants of Greenwich mean time from such stations as the Eiffel Tower, Lyons, Nauen, Annapolis, Darien, Honolulu and Cape Town, and it should be possible to pick up one or more of these signals at any point on the earth's surface. The time shown by a chronometer can, therefore, be checked by wireless at least once a day, and since the astronomical observations made by a navigator for ascertaining local time are accurate only to 1' of arc, corresponding to 4 sec. of time, a chronometer which can be relied on to within 4 sec. a day is sufficient. This is far within the limit of modern chronometers.

A new method of determining positions on the earth's surface, independently of time altogether, has recently become possible, although it is still far short of attaining the desired degree of accuracy. The direction of a wireless transmitting station can now be determined by the receiving station to within about 3°, and if the directions of two transmitting stations are known the position of the receiver can be found. Accuracy is of course greatest where the two transmitting stations subtend a wide angle, and the best results are obtained when the wireless waves can be sent out from the point, the position of which is to be determined and the directions found by two land stations. The method promises to be of great service in aerial navigation, and for ships near the coast in foggy weather. In the beginning of 1921 nine wireless direction stations in the British Isles, sixteen in France, four in Germany and one in Italy were available for navigational purposes.

The position of buoys in the North Sea has been determined by the time required by sound to reach special receiving apparatus at fixed points on the coast. This method was introduced soon after the Armistice in Nov. 1918, but its application is limited to distances of 100 or at most 200 miles.

Accurate Determinations of Time and Longitude.—The precision of time observations has been greatly increased by the use of the self-registering micrometer in observing transits. With this micrometer the personality of different observers is reduced to 0.01 to 0.02, so that the exchange of observers for longitude determinations is only necessary in work of the very highest accuracy. The sending and receiving of rhythmic wireless time signals has reached such a degree of accuracy that the clocks at distant stations can be compared to 0.01 or less. It should therefore be a simple matter to make accurate longitude determinations. The value of the new methods was fully established in the determination of the difference of longitude between Paris and Washington in 1913-4, when the result obtained was $5^{\circ}17'36.653''$ = 1003.

Standard Time—The use of a system of zones of standard time has been considerably extended.

Greenwich time is now (1921) adopted in the British Isles, Spain, Portugal, Belgium, France and the Faroe Islands. Mid-European time (1 h. fast on Greenwich) is used in Germany, Denmark, Italy, Switzerland, Norway, Sweden, Austria and the western parts of the Balkan peninsula; and E. European time (2 h. fast on Greenwich) in the eastern parts of the Balkan peninsula, including Greece. Time in Iceland is 1 h. slow on Greenwich. Russia still adheres to Pulkovo (Pulkowa) time, 2 h. 1 min. fast on Greenwich. Divisions of less

than an hour are used in several British colonies. Standard time in the E. African Protectorate is 2 h. 30 min., in India 5 h. 30 min., in Indo-China 6 h. 30 min., in S. Australia 9 h. 30 min., in New Zealand 11 h. 30 min. fast; in British Guiana 3 h. 45 min., the Sandwich Is. 10 h. 30 min., Samoa 11 h. 30 min. slow. In all other countries adopting standard time the most suitable whole hour is employed. The standard zones in Brazil are from 2 to 5 h. slow on Greenwich. Uruguay, the Argentine Republic and Siam adopted standard time in 1920.

In the United States in 1918 to the four zones already established (1883) was added a fifth for Alaska alone. Standard time for this zone is based on 150° W. longitude. Standard time in the four other zones is based, as from the beginning, on the 75th, 90th, 105th, and 120th meridians. The marking of the limits of the various zones lies with the Interstate Commerce Commission, and they may be changed at its discretion. The first four zones differ from each other 1 h. in standard time, the fifth differs from the fourth by 2 hours. The first zone is 5 h. slow on Greenwich.

Until recently no definite time system was employed at sea, each ship adopting the local time corresponding to its position at a certain instant, usually noon. In 1919 a system of hour zones similar to that used on land, previously adopted in the French and Italian navies, came into official use in the British navy, a change which will greatly facilitate the interpretation of entries in ships' logs. The "zone description" of each zone is denoted by a positive or negative number equal to the number of hours slow or fast on Greenwich.

The central zone or Zone 0 lies between long. 7½° E. and long. 7½° W.: the zones to E. of this are numbered -1, -2, -12, and those to W. +1, +2, +12. Zone 12 is divided centrally by the 180th meridian (the date line) and the + or - prefixes are used in its two halves. Near land the boundaries between the zones are modified so as to agree with the time used ashore.

Civil and Astronomical Times—The civil day reckoned from mean midnight, instead of the astronomical day reckoned from mean noon, is to be adopted in the *Nautical Almanac* in 1925, and a similar change has been decided on for the *Connaissance de Temps* and the *American Ephemeris*. The same course will probably be followed by astronomers, but some confusion may arise if the old expression "Greenwich Mean Time" is employed in a new sense.

TINAYRE, [MARGUERITE SUZANNE] MARCELLE (1872-), French novelist, was born at Tulle, Corrèze, in 1872. She was educated at Bordeaux and Paris, and in 1889 married the painter Julien Tinayre. Her earliest novel was *Avant l'Amour* (1897), but the one by which she is best known is *La Maison du Pêche* (1902). Her later works include *La Rebelle* (1905); *La Consolatrice* (1907); *Madeleine au Miroir* (1912); *L'Ombre de l'Amour* (1910); *La Douceur de Vivre* (1911); and *Le Départ; Adieu, 1914* (1915). She also published in 1910 a book of travels, *Notes d'une Voyageuse en Turquie*.

TIRE (see 26.1006).—The modern motor vehicle (see **MOTOR VEHICLES**) would not be possible without some cushioning or shock-absorbing medium at the periphery of its wheels. India rubber, properly fashioned and fabricated with metals and fabrics into tires, plays an essential part in providing this necessary cushion. Structurally, tires are divided into two main classes—solid rubber and pneumatic. The cushioning properties of solid

FIG. 1.

tires are due to the elasticity of the rubber and the design of the tread, while in the pneumatic type compressed air is the cushioning medium, the rubber tire in this case serving as a flexible, yielding container for the compressed air. In both classes the

various types are made in a progression of sizes, varying in outside diameter to give the proper road clearance, and in width to accommodate properly the weight the tires have to support.

History from 1910 to 1921—This period opened with the motor vehicle industry served by clincher or beaded edge pneumatic tires (fig. 1) of square woven fabric not larger than 5½ in. in section, suitable for use on passenger cars only, and giving 3,000 to 4,000 m. service. The trend of tire development had only recently settled on this clincher type as the most logical of the many inventions, and the shortcomings of the product were varied and numerous. Americans, following British design, were especially unfortunate in having a great deal of premature failure due to "rim cutting." This clincher type was also difficult to apply to the rims in the larger sizes, and troublesome security bolts were necessary to keep the tire from creeping around the rim. Progress in tire development has been influenced by three considerations: first, the method of attachment to the rim, second, increase in the durability of the tire; and third, the development of new types of tires for new fields of usefulness. The principle of the Dunlop-Welch wired-on bicycle tire had been tried experimentally in motor vehicle tires by using a bulky inextensible wire bead fastened to the wheel rim with "straight-side" bolted-on flanges. This straight-side tire idea first became practical for motor vehicle use in 1907 when an American manufacturer offered to the American public in perfected form his

FIG. 2.

"detachable" straight-side rim and tire. Its progress was slow because of competitive hindrances, but by 1910 the detachable rim had become so much appreciated that the clincher tire manufacturers were obliged to furnish some sort of a detachable tire. The result was the "quick-detachable" (Q.D. clincher), a tire fitting a detachable clincher rim and having its beads shaped like the regular soft bead clincher but with an inextensible wire bead core like the straight-side tire. During this period of development the Q.D. clincher served admirably as a transition type.

The merits of the straight-side (fig. 2), however, gradually made it more popular than the Q.D. clincher, with the result that the last Q.D. clincher rims were made in 1916. In the meantime the European demand continued to be for the clincher type exclusively, while except in the Ford sizes, they were discontinued in American production. American army vehicles and motor vehicles exported on straight-side tires have recently opened a market for straight-side in other countries. The year 1921 found the situation as follows: bicycles were fitted with single tube tires in America and wired-on tires in Europe.

Motorcycles were fitted with clincher tires both in America and Europe, and aeroplanes with either clinchers (fig. 3) or wired-on according to the demand. Passenger cars were fitted with European Standard clincher tires for European productions. Amer-

FIG. 3

ican small cars took 33-in American Standard clincher tires, while cars using larger than 33-in took American Standard straight-side tires. All American "motor trucks" using pneumatics operated on straight-side tires, and for solid tire equipment took pressed-on, channel base tires (fig. 4).

FIG. 4

European "lorries" were fitted with the typical English band tire (fig. 5). Progress in details of design, materials, and methods

of manufacture was very gradual, the general idea being always to build a "balanced" tire, that is, one in which all parts were equally durable. There are practically no formulae or theories on tire design (except the rubber compound formulae) of value to

FIG. 5.

the tire manufacturer, whatever good qualities any particular make of tire embodies are the result of persistent and constant experimentation, combined with the policy of the individual company controlling the standard of quality which it desires to offer to the public. The square woven tires of 1920 averaged 5,000 to 6,000 m. of service. There was one outstanding development during the period 1910-20, namely, the "cord construction." The cord idea was old, having been used in bicycle tires in the 'nineties, but the "square woven tire duck" appeared to be more practical for motor vehicle tires.

About 1912 electric automobiles in America created a demand for "power saver" tires to which the tire makers responded by offering special casings of cord fabric structure for which exceptional resiliency and lack of internal friction were claimed. Not at all durable at first, as they were gradually perfected the leaders of the industry became convinced that this was to be the quality tire of the future (fig. 6).

FIG. 6.

Ply separation and fabric breaks in cord tires are effectively prevented because the cords, being completely insulated from each other, provide a flexibility of the "carcass" without chafing,

that greatly reduces injury from under-inflation and overloading. Development in the two-ply "cable" cord construction and the "multi-ply" construction paralleled each other. In 1920 the merits of the multi-ply construction had prevailed to such an extent that the "cable" cord was no longer made. After the World War European tire manufacturers began to duplicate American multi-ply cord construction in their millimeter beaded edge sizes. The cord tires of 1920 averaged 7,000 to 8,000 m. of service. Durability was also materially improved by increasing the cross-section size of the tires. In 1920 practically all American straight-side cord tires were made 10% over the nominal size. Also the tire manufacturers gradually succeeded by persistent educational work, in getting car manufacturers to fit tires adequate for the loads to be carried. During this decade a new use was developed for pneumatic tires, namely their application to motor trucks up to 3½ tons capacity. The movement made very little progress from 1910 to 1915. "Dual" (or twin), square-woven fabric tires in passenger car sizes were first tried. Then square-woven fabric tires of 8-in. and 9-in. sections were employed with results encouraging enough to justify putting a limited number on the market. By 1916 automobile cord tire construction had been mastered sufficiently for trial in the truck sizes. Success with 6-in., 7-in. and 8-in. sections immediately demonstrated the superiority of the cord construction and was followed by regular demand from the public. The 9-in. and 10-in. sections were used to some extent but their future was in 1921 uncertain. The typical solid tire of 1910 was the British "pressed-on" band tire then in use in Europe and soon to be duplicated in America. These tires were fitted to the wheels by simply forcing or pressing on with a special press, but in the absence of conveniently located tire presses, some American manufacturers adapted the metal base idea to a "bolted-on" design (called "Demountable"), having bevels on the inside edges of the steel band so arranged that hoop-shaped "wedges" could be fitted to mount the tire, the whole assembly being bolted in place with "side flanges". Early metal base tires in America failed prematurely from fracture of the exposed hard rubber at the edge of the base band due to rough streets. To remedy this the band was made in "channel" form and the hard rubber protected by the side of the channel. In 1913 as an experiment, a "channel base" tire made to press directly on the S.A.E. (Society of Automotive Engineers) standard wheel without traction plate or staples, previously considered necessary, was tried. The experiment was successful, and this new type was so much simpler and less expensive that it rapidly superseded all other types in America. In 1915 wide single solid tires were introduced in America (8 in., 10 in., 12 in. and 14 in. wide) on the rear of heavy trucks in place of dual or twin tires. In 1920 wide singles and duals were almost equal in popularity.

The growth of pneumatic tire production in the United States is shown by the following figures, those for 1913, 1914, 1915, 1918 and 1919 being estimates:—

1913	6,588,000	1917	25,845,656
1914	8,983,000	1918	21,000,000
1915	12,840,000	1919	35,000,000
1916	18,564,957	1920	32,400,000

Structure, Materials and Manufacturing.—Solid tire structure is clearly shown in figs. 4 and 5. The tire maker's problem is to attach the tread rubber, which must be of highest quality, to the wheel. This necessitates a steel foundation band, a thin layer of hard rubber specially compounded to adhere to the steel, to which the tread rubber will also adhere. No practical way of making the tread rubber adhere to the steel is known. The component parts of the straight-side pneumatic tire are indicated in figs. 2 and 6. The bead portion has imbedded in it a circular inextensible wire core, usually of many strands in the form of braid, cables, or coils (to give a certain amount of flexibility). This wire anchors the tire to the rim, prevents it from blowing off, and gives rigidity enough so as to prevent the tire from creeping on the rim when inflated. The body or "carcass" of the pneumatic tire consists of bias "plies" of cotton fabric impregnated with adhesive rubber "friction," insulated from each other by a thin "skim coat" of the rubber, and having the edges of the plies folded or "tied in" alternately over and round the wire head core. (See fig. 7 showing detail of a typical bead "tie-in.")

Since the function of the carcass is to serve as a strong yet flexible container for the inner tube with its charge of compressed air,

the specifications covering the fabric call for great strength, uniformity of weight, freedom from grit, and particular grades of long staple cotton (Arizona, Sea Island, Egyptian, Sacalardes, Pealer, etc.) The two general classifications are: first, "square-woven" fabric, weighing 17½ oz. per sq. yd., woven from warp and filling, twisted of 11 strands of No. 23 yarn and having a tensile strength

FIG. 7.

of 425 lb per in. of width (both warp and filling) for the best fabric. The number of plies used are 3½-in. 4-ply, 4-in. 5-ply, 4½-in. 6-ply, 5-in. 7-ply. Second, "Cord" ply-fabric, which is primarily a warp composed of parallel cords of combed Arizona or Sea Island cotton resembling fish line and weighs 14 oz. per sq. yard. The parallel cords would get snarled up in the tire building processes, so for handling purposes it is necessary to weave a single light filling thread into the cord, 2½ picks per inch. Each cord, ((23)5/3) cabled yarn, has a tensile strength of 20 lb. In cord tires the cords of each ply must cross those adjacent, consequently the direction of the bias is reversed in the successive plies, which number as follows: 3½-in. 4 plies, 4-in. 6 plies, 4½-in. 6 or 8 plies, 5-in. 8 plies, 6-in. 8 or 10 plies, 7-in. 10 plies, 8-in. 12 plies, 9-in. 14 plies, and 10-in. 16 plies. As mentioned above, the tire plies are "tied in" round the wire bead core. To make a bead proof against rim cutting, etc., the most improved designs include narrow reinforcing strips of frictioned fabric (see figs. 1 and 7). The outermost of these is named the "chafing" strip. The outside of the carcass is entirely covered with rubber, the sides with a "sidewall" layer, ⅞-in. thick, and at the tread portion with "cushion stock," "breaker fabric," "undertread," and "tread." The tread is the thick, tough, firm, wear-resisting face of the tire which is in contact with the road surface. The forces and stresses of vehicle operation are so severe in their tendency to tear the tread from the carcass that tire makers have found it impracticable to attach the tread directly to the carcass, and have had to resort to the interposition of the soft elastic adhesive "cushion" and open mesh "breaker fabric" to taper off the severity of the shearing stresses that would loosen the tread. Another very important function of the cushion and breaker is to prevent fabric rupture of the carcass by softening and spreading the intensity of impact of rough roads. The design and quality of the tread rubber must be worked out to wear at least as long as any other part of a balanced tire. The simplest smooth tread is a thin crescent in cross section; and in the case of non-skid designs they are generally crescent cross section with geometrical depressions or protuberances. The physical properties most desired are toughness, to resist cutting and chipping, and attrition resistance to provide against abrasion from road surface friction.

There are no particular differences of design for the inner tubes; nearly all makes resemble each other very closely. Highest quality rubber with little or no compounding except sulphur is used for grey tubes. The best red tubes are compounded with antimony sulphide. To be satisfactory the tube must hold air; not crack nor check in storage, not stretch out of shape; not stick to the casing; not split nor tear easily; not be affected by heating; and must be repaired easily. "Flaps," made of inexpensive rubberized fabric, are used in straight-side tires to prevent the tube from being pinched or nipped under the edge of the bead, and to keep water and rim rust away from the tube.

Only general ideas of manufacturing can be mentioned. First, there is "stock preparation"; the rubber and "compounds" are mixed, the fabrics "frictioned" and "skimcoated" with rubber, gauged to a very exact thickness, the frictioned fabrics cut to proper widths on a machine called the "bias cutter," the cushion, undertread, and sidewall stocks are sheeted out and cut to width on the calender, the tread rubber is prepared either on the calender or the

"tubing" machine, and the bead wires are padded with rubber and frictioned fabric and cold pressed into shape. (See RUBBER for stock preparation.) "Building" the tire is the next step. A "core" in shape and size like the inside of a finished tire used as a building form, is mounted on a stand which permits the core to revolve. The tire plies are drawn taut around the core and rolled down smooth one after another, and at the proper time the bead is put in position. After the last ply is in place the tie-in at the bead is made; the building is finished by adding the sidewall, cushion, breaker strip and tread. During the decade 1910-20 tire building changed from all hand work to a combination of hand and machine building. In addition to saving labour, the machines turn out more perfect work. The final step is the vulcanizing or "curing." Fundamentally this is simply the processes of subjecting the "uncured" tire to a definite degree of heat for a definite length of time while the tire is confined under pressure in a strong iron "mould" (with an iron "curing core" or inflated "air bag" inside the tire). The heat effects chemical changes in the rubber compounds just as in cooking. Quality in a tire is very dependent on the curing. Not only must there be an optimum cure but the mould pressure must not disturb the fabric lest "buckles" or "mould pinches" be formed. This last is so important that many manufacturers resort to the more expensive double cure process—the carcass is semi-cured to "set" the rubbers and fabrics with much less danger of fabric displacement, after which the tread is cemented in place and the cure finished.

Tire Troubles.—For the purpose of general analysis in pneumatic tire service, five major tire troubles are recognized. They are (1) unsatisfactory tread wear; (2) separation either (a) between plies of fabric or (b) of tread from carcass; (3) fabric ruptures; (4) bead troubles; and (5) tube troubles. In each case it is possible to classify pretty completely the origins of the mischief. Of course, many instances of premature tire failure are due to defects of design, materials or manufacture; on the other hand, by far the more frequent cause of tire trouble is abuse in the hands of the user as outlined below:—

Unsatisfactory Tread Wear	} caused by	Abrasion Wheels out of alignment Too much power Improper use of brakes Skidding Abrasive road surfaces Under-inflation Sharp stones cutting tread Deterioration from oil
		Excessive flexing Riding under-inflated Riding car tracks Overloading Riding flat Abuse of rough roads Cuts Heating from speeding Water-soaked fabric
Separation (a) between plies of fabric (b) of tread from carcass	} caused by	Overload Over-inflation Under-inflation Stone bruises Premature ply separation Cuts Exposed fabric water-soaked Speeding on rough roads
		Bent rims Under-inflation
Fabric Ruptures	} caused by	Riding flat Leaky valves Puncture Heating from speeding Pinching under bead Tears from rough handling Neglect of spare tube
Bead Troubles	} caused by	
Tube Troubles	} caused by	

Solid tire troubles are confined to premature wear in the form of cutting, chipping, and breaking large chunks out of the tread; disintegration in the heart of the tire due to the accumulation of the heat of internal friction on long trips (rubber is such a poor conductor that heat is not adequately dissipated by windage); and separation of the whole mass of the tread rubber from the steel base-band. This last is a defect in materials or manufacture except in cases where external abuse fractures the hard rubber. In order to cushion a specific load properly a tire must not have too high air pressure; on the other hand, under-inflation results in excessive flexing which in turn brings on premature ply separation and fabric breaks. Experience has demonstrated that a pneumatic tire should not flex more than 11% (for large tires) to 15% (for small tires) of the section diameter of the tire. Recommendations designed to advise vehicle manufacturers and users as to the proper conditions under which the tires should be used are given in their "carrying capacity" schedules, as indicated in the following table

Carrying Capacities and Inflation Pressures of Pneumatic Tires
S.A.E. Standard

Tire Size	For passenger cars				For commercial vehicles

(J. E. HA.)

TIROL (see 26.1010), an Austrian Territory, divided by the Treaty of Peace of St. Germain into two separate parts—*Northern Tirol* and the district of *Lienz*. Northern Tirol is bounded on the E. by Salzburg, on the N. by Bavaria, on the W. by Vorarlberg and Switzerland and on the S. by Italy (German Southern Tirol). It lies mostly in the valley of the Inn, the northern part in the Kalk-Alpen and the southern in the schists and the central zone of the eastern Alps. The southern frontier almost coincides with the watershed between the Inn and the Adige. In the N., Tirol extends into the basins of the Lech and the Isar. The "Fohnstrasse" of the Brenner renders the cultivation of maize possible in some parts of the Inn valley. The new Territory has an area of about 4,787 sq. m. and its pop. was in 1910, 304,713, in 1920, 306,156 (64 per sq. mile). The area of the Lienz district is about 763 sq. m.; pop. in 1910 about 29,000.

The population is almost entirely German and Roman Catholic (1910, 98.9%). The proportion of males to females in 1910 was as 1,000 to 981 but in 1920, 1,000 to 1,053.

For administrative purposes Northern Tirol is divided into seven districts and the autonomous city of Innsbruck, the capital (pop. in 1920 55,659). Lienz is a district of itself. Other important places besides Innsbruck are Holting bei Innsbruck (pop. 9,503), Schwarz (pop. 7,385), Hall (pop. 6,984), Kufstein (pop. 6,662), Lienz (pop. 5,756), Wörgl (pop. 4,030), Landeck (pop. 3,919).

Agriculture and Forestry.—In 1910, 23.7% of the present Tirol was unproductive. Of the productive areas (1910), 5.9% was arable, 0.2% gardens, 7.4% meadows, 41.5% pasturage (almost entirely high summer grazing lands) and 44.9% forest.

Cattle-raising and farming on the high lands are well-developed industries, although less care is bestowed on them than in Switzerland. But in 1918 there were only 159,398 head of cattle (of which 91,219 were cows) and 24,421 swine. The Tyrolean breeds of cattle are highly esteemed. Forestry also holds an important place among the industries of this Territory.

Minerals.—The salt mines yielded 15,000 tons in 1915 (9% of the whole Austrian output) at Hall bei Innsbruck. The production of lignite, 40,000 tons in 1915 (scarcely 2% of the Austrian output), is chiefly from Häring in the Unter-Innthal. Copper, lead, zinc, antimony and sulphur and asphalt are also mined.

Manufactures.—Industry is still little developed although the use of the abundant water power is rapidly increasing; there are electrical stations at Innsbruck and elsewhere. Mention should be made of the wood, iron, textile, earthenware and glass industries. Innsbruck is as yet hardly an industrial city but has commercial importance and is visited by great numbers of tourists.

Communications.—Mountain railways from Innsbruck to the Stubai-Thal and to Mittenwald, the junction for Munich, have led to a great development of tourist traffic and are of marked importance for trade and industry.

TIRPITZ, ALFRED VON (1849—), German admiral and politician, was born at Küstrin March 19 1849. He entered the Prussian navy in 1865, and by 1890 had risen to be chief-of-staff of the Baltic station in the Imperial navy. In 1892 he was in

charge of the work of the chief-of-staff in the higher command of the navy. He was promoted to be rear-admiral in 1895, and in 1896 and 1897 he was in command of the cruiser division in east Asiatic waters. In 1899 he reached the rank of vice-admiral and in 1903 that of admiral. For the long period of 19 years, from 1897 to 1916, he was Secretary of State for the Imperial navy, and in this capacity advocated the navy bills of 1898, 1900, 1907 and 1912 for increasing the German fleet and successfully carried them through the Reichstag. In 1911 he received the rank of grand-admiral, and he retired in 1916.

The best account of Adml. von Tirpitz's naval achievements and political activities is contained in the book which he published in 1919 under the title of *Erinnerungen*. In that book he shows how gigantic was the task of creating the new German navy with which Great Britain had to reckon at the outbreak of the World War. Not only had a whole array of subsidiary industries to be established and supplies of raw materials secured; thousands of skilled workmen and hundreds of directing personalities of strong character and exceptional ability had to be found and trained. It has been customary to attribute the creation of the German navy to the Kaiser William II., and it is true that in large part the initiative for successive increases, and the demagogic appeals by which they were supported, originated with the Emperor. On the other hand, it was Tirpitz who not only conducted the practical advocacy of these schemes in the Reichstag, but also organized the service of propaganda in the German press and on the platform, putting popular pressure on the parliamentary representatives of the nation and constraining them to agree to the enormous expenditure which these schemes entailed. William II. was often a hindrance as well as a help, and Tirpitz gives instances in which the work of the construction departments and even that of the Secretary of State were interrupted or hampered by wild-cat Imperial projects for the construction of architecturally impossible vessels or of mechanically impossible machinery. One of these projects, on which an elaborate report had actually to be submitted to the Emperor, was a device for which it was claimed that it had solved the problem of perpetual motion. In the conduct of the naval war the official rôle of Tirpitz was confined to reporting and advising at general headquarters, the actual conduct and initiative in operations being in the hands of the higher command of the navy at Wilhelmshaven, subject to the Emperor's approval or veto. Tirpitz advances two contentions; first, that he would have sent the navy into decisive action at an earlier stage of the war, secondly, that he would have made an earlier and more ruthless use of the German U-boats, but his opponents traverse both these claims, and in particular assert that as Secretary of State he had neglected the construction of submarines, so that Germany entered the war with a comparatively small supply of these vessels.

In the political sphere Tirpitz was a bitter opponent of Bethmann Hollweg, whom he charged with indecision, half-heartedness and nebulous conceptions of the necessities of German policy. His own experiences in the Reichstag, and the close contact with the political parties which his advocacy of successive naval bills had involved, made him a master of political intrigue. During the years which immediately preceded the war, as well as during the first 18 months of the conflict, he was himself a candidate for the office of Imperial Chancellor, in the sense that many of the reactionary Conservatives and of those who advocated a ruthless conception of policy in peace and war regarded him as their political hope. Lord Haldane, in his book *Before the War* (1920), records his impression of Tirpitz when he visited Berlin in Feb. 1912 in order to make tentative proposals for an agreement regarding the limitation of new construction. Bethmann Hollweg, Lord Haldane thought, was willing to entertain the British suggestions, it was Tirpitz who behind the scenes offered a most strenuous opposition to any restrictions. Tirpitz himself maintains that his naval aspirations were directed not towards a war with Great Britain, but to the creation of a state of naval equilibrium & of German superiority, which would have enabled Germany to insist upon the unreserved cooperation of British policy in her world aims. It was probably true that Germany's policy was

directed rather towards being so strong at sea as to make England unwilling to fight her unless absolutely necessary, than towards actually challenging British naval supremacy. But this policy was, in any case, bound to make England peculiarly sensitive to provocation by Germany,—a point which was ignored by the champions of a great German navy. Tirpitz's book, in so far as his statements may be trusted, throws much light upon the circumstances in which German policy was directed or drifted in July 1914 into paths which inevitably led to war. He enlarges in particular upon what he considers the folly of the declaration of war upon Russia (see BETHMANN HOLLWEG). He is naturally influenced to some extent in what he says by his poor opinion of Bethmann Hollweg's capacities and by his own thorough knowledge of the Emperor's fickle and impetuous character.

His resignation in 1916, and the stages of his relations with the Emperor and the Higher Naval Command which led to it, are described in his *Erinnerungen* with almost tragic vividness. Tirpitz remained a leading figure in the political agitation against the Chancellor's policy and was selected as president of the "Vaterlandspartei," a political association started in Sept. 1917 under reactionary auspices to combat all attempts at peace by compromise, and to advocate the prosecution of the U-boat warfare with extreme ruthlessness. This association offered a vigorous opposition to the movement, which succeeded only when it was too late, for obtaining alterations in the constitution limiting the power of the Emperor and laying the foundations of real parliamentary government in the Empire and in Prussia.

After the revolution Tirpitz was one of those against whom German popular animosity was chiefly directed as being the inspirer of the naval and world policy which led to the war, and also the most powerful influence in prolonging it. He was one of those who found it inadvisable to remain in Germany, and he departed to find a refuge in Switzerland. After the republican Government seemed fairly established, and the reign of law and order was being restored, he returned, but, possibly on account of his advanced age, did not appear during 1921 to be taking any further part in political intrigue or agitation. (G. S.)

TISZA, STEPHEN, COUNT (1861-1918), Hungarian statesman (see 26 1017). During the Coalition Ministry (1906) Tisza retired into private life on his estate of Geszt. It was only in the House of Magnates that he expressed his views against the extension of the franchise. When Count Khuen-Hedervary took office in 1910, Tisza was his most earnest and effective opponent in the country. His return to the political arena took place during a period of obstruction. In 1912 he became president of the House of Deputies, and on July 10 1913 again returned to power as prime minister. When the World War broke out a truce was arranged between Tisza and the Opposition, but it did not last long, and in 1917 he was compelled to resign. Though hitherto he had been the most zealous adherent of Dualism and the partnership with Austria, he declared for the scheme of personal union after the manifesto of King Charles on Oct. 17 1918, the Pragmatic Sanction to hold good on the question of national defence, but with a separate Hungarian army and separate diplomatic representation abroad. When he saw no prospect of winning the war he pleaded for a peace in common with Germany on the basis of President Wilson's Fourteen Points. On Oct. 31 he was assassinated in his villa by men in military uniform, said to have been worn as a disguise.

Tisza had a power over Austria and Hungary such as had hardly ever been exercised before by an adviser of the Crown. He was distinguished by his determination and inflexible convictions, and was opposed to any policy involving weak concessions. In the newspapers *Magyar Figyelő* (Hungarian Observer) and *Ignazmondó* (Truth), he published articles on many subjects; in addition he published the historical study *Von Sadowa bis Sedan* (in Hungarian and German).

See the biography by Karl Szaz (Hungarian); and David Angyal, *In Memory of Stephen Tisza* (Hungarian). (E. v. W.)

"TITANIC" DISASTER, 1912.—No single event in 1912 could compare, in the intensity of its universal appeal to human

emotion, with the awful disaster to the British steamship "Titanic" At 2.20 A.M. on April 15, that great White Star liner, the largest afloat, on her maiden voyage, went to the bottom of the Atlantic in lat. 41° 46' N., long. 50° 14' W., about 2½ h. after striking at full speed on an iceberg, with a loss of 1,513 souls out of 2,224 on board.¹ It had been supposed that such a vessel was unsinkable, and the tragedy raised numerous questions as to methods of ship construction, and additional provision of life-saving equipment. The "Titanic" had nominally boat accommodation for double the number saved, and the 20 boats launched were meant to hold 1,178 persons instead of the 652 they actually contained when they left the ship; moreover, the disaster occurred under exceptional conditions for getting people safely off, in the way of smooth water and fine weather. The most salutary lessons seemed to lie in the following directions: first, improved design and construction so as to provide a really unsinkable ship; secondly, greater precautions in navigation and look-out—for the "Titanic" was going at 18 knots (according to Lord Mersey an "excessive speed"), though it was known that icebergs were exceptionally numerous on the course; thirdly, better and more regular organization on shipboard—by boat drill (there had been none on the "Titanic") and otherwise, for the emergency of having to abandon ship; and fourthly, a compulsory service of wireless on all liners, working day and night—for it was one of the most lamentable incidents in the whole terrible story that the "Titanic's" wireless call for help, picked up all over the ocean and nobly responded to by the "Carpathia" (Capt. Rostron), 70 m. off, fell on deaf ears on the "Californian" only 8 or 10 m. away.² The full record of the disaster is contained in the reports of the inquiries held at once in America by a committee of Congress under Senator Smith, and later in London by a special commission presided over by Lord Mersey (report issued July 30). Painful and difficult though it was to distribute blame in such a case, there could be little doubt that the loss of life—817 passengers out of 1,316, and 606 out of a crew of 908—was much greater than ought to have been possible. Capt. E. J. Smith (b. 1853), a highly experienced seaman, who had been for 38 years in the service of the White Star Co. and who now went down with his ship, seems to have been averse from taking steps at first which might cause a panic on board; otherwise there should have been time, if adequate means of organization and of commanding discipline had existed, not only to get more people into the boats but to improvise rafts. In naval circles the opinion was strongly held that this should have been done, since the injuries received by the ship made it certain that she would sink in a given time. If so, there was a weakness in the higher command, or the means provided for exercising it in the organization of the crew on the "Titanic," for which no merely material equipment could compensate. A natural expectation of security had been engendered, alike among the owners, officers and passengers of these magnificently appointed liners, which, until a crisis actually came, had made it almost unthinkable that it could come in that way; but the fact remains that responsibility for the lives of passengers rests with those who control the ship. In this case, it was not the inadequacy of the physical means of escape that accounted for the large proportion of the lost who remained on board, it was the inadequate organization for purposes of using them, and inadequate information as to the necessity. Apart from that, both Great Britain and America could mingle sorrow and pride over many fine incidents of the tragedy, with its long death roll of prominent people from both sides of the Atlantic. When it came to the sending away of the boats, the order was

¹ The exact figures remained doubtful, but those given are from Lord Mersey's report.

² Apart from the "Californian's" wireless operator having gone to bed, however, Lord Mersey was satisfied that if her captain had realized the situation properly she could have saved "many, if not all, of the lives that were lost"; for evidence showed that distress rockets sent up on the "Titanic" were actually seen from the "Californian," though no action was taken in response to them. The incredibility of such a disaster appears, in that case, to have paralysed the capacity for interference.

"women and children first." The figures of the 711 saved by the "Carpathia" (including about 60 who were picked up in the boats after the ship went down) speak for themselves:—Women: first class, 140 out of 144; second class, 80 out of 93; third class, 76 out of 165, crew, 20 out of 23. Children: first class, 6 out of 6; second class, 24 out of 24; third class, 27 out of 79. Men: first class, 57 out of 175; second class, 14 out of 168, third class, 75 out of 462; crew 192 out of 885. Altogether the percentage of women saved was 74.35, of children 52.29, of men 20.27. The comparatively small proportion of third-class passengers saved was shown to be purely accidental and not due to any preference being deliberately given to others; they were handicapped, however, by their quarters being remote from the boat deck, and by so many of them being unable to speak or understand English.

TITTONI, TOMMASO (1855—), Italian statesman, was born in Rome 1855. His father, Vincenzo, a tenant farmer on a large scale at La Manziara, had taken part in the defence of the Roman Republic under Garibaldi in 1849, was exiled by Pius IX, and reentered Rome in 1870 through the breach of Porta Pia. Tommaso Tittoni was educated first at Naples, and subsequently at Oxford and Liège. He began his parliamentary career as deputy for Civitavecchia in 1886, sitting on the Right, but he resigned his seat in 1897, having been appointed prefect of Perugia; three years later he went to Naples in a similar capacity, and in 1902 he was raised to the Senate. When Giolitti became premier for the second time in 1903, Tittoni became his Foreign Minister. He aimed at improving relations with Austria, and also tried to bring about a reconciliation with France, it was in fact under his auspices that President Loubet visited Rome. On the resignation of Giolitti in March 1905 Tittoni became interim premier for a few days and remained in the Fortis Cabinet as Foreign Minister. His proposal to reduce the duty on Spanish wines in connexion with an Italo-Spanish commercial treaty aroused a storm of indignation among the agricultural classes and caused the fall of the Cabinet on Dec. 24 1905; and although Fortis composed a new administration, Tittoni did not enter it. A few months later he was appointed ambassador in London (March 1906), but in May, on the fall of the Sonnino Cabinet and the return of Giolitti to power, he was again summoned to the *Consulta*. He continued the policy of improving relations with Austria, which did not contribute to his popularity; after the annexation of Bosnia and the Herzegovina his imprudently worded speech at Carate created the illusion that Italy was to be compensated, perhaps by the cession of the Trentino, and the disappointment when nothing of the kind materialized greatly weakened his prestige. He remained in office until the fall of Giolitti in Dec. 1909. In April of the following year he was appointed ambassador in Paris. When the World War broke out, in spite of his Triplicist policy he openly expressed himself in favour of Italian neutrality, and on Italy's entry into the war he was careful not to compromise himself with Giolitti's attitude. But he was not at his ease in the French capital and in Nov. 1916 he resigned from the Paris embassy. On the fall of the Orlando Cabinet in June 1919, the new Premier Nitti chose Tittoni as Foreign Minister and first delegate at the Peace Conference, but the severe strain of the work told on his health and he was forced to resign in November. He was chosen president of the Senate in Dec., and soon after was appointed Italian delegate on the Council and Assembly of the League of Nations, but ill-health again forced him to relinquish both appointments. In 1910 he had published a volume of speeches, which was translated into English, and in 1919 he brought out a work on political conflicts and constitutional reform.

TOBACCO (see 26.1035).—In 1913 the quantity of tobacco retained for home consumption in the United Kingdom was: unmanufactured 94,079,343 lb., and manufactured 1,896,668 lb. The year 1914 showed the beginning of the abnormal business in the factories. In that year, apart from tobacco sent to H.M. forces through the bonded factories, the quantity retained for home consumption was: unmanufactured 99,415,786 lb., and manufactured 1,585,411 pounds. In 1915 the amount of unmanufactured

tobacco retained for home consumption rose to 206,516,337 lb., the following year it was 201,710,100 lb.; and then from 1917, when the total was 204,501,452 lb., the amount went to 206,566,549 lb. in 1918 and to no less than 142,826,314 lb. in 1919. With imported manufactured tobacco, including cigars, cigarettes and snuff, the total consumed in 1919 was 145,344,604 lb. In 1914 the amount of unmanufactured tobacco which went through the factories and was consumed represented a consumption per head of population of 2.16 lb., in 1919 it was 3.09 lb. per head.

The imports of tobacco into the United Kingdom by no means follow in the same ratio as the figures of consumption. When the World War broke out, thanks to the tradition of the trade and the prudent foresight of manufacturers, there were large stocks in the country. In view of the heavy requirements, fresh importations of raw tobacco were secured as before, but when the submarine activity added to the already urgent call upon shipping, imports dropped off very considerably and tonnage was only allowed sparingly for tobacco freights. The import of unmanufactured tobacco in 1913 was 162,365,925 lb.; in 1914 it was 158,692,857 lb.; 1915 202,650,863 lb.; 1916 164,265,861 lb.; 1917 40,543,000 lb.; 1918 171,639,313 lb. and in 1919 348,906,624 lb. It will be seen that the curve of imports drops in 1916 and is much lower still in 1917, and that so soon as shipping became available the depleted stocks of manufacturers were promptly renewed. Manufacturers had been purchasing but shipment had been held up. In addition to the manufactured tobacco imported in 1919, the following manufactured products were also brought into the country in that year: cigars, 1,670,735 lb.; cigarettes, 4,460,535 lb.; other tobacco, including snuff, 1,755,447 lb.

Before examining the Control Board's activities and retail prices in England it is interesting to note how the Treasury got on in the matter of revenue and under the influence of taxation which was several times heavily increased. The net receipts of British Government revenue in each year ended March 31 were as follows: 1913-4 £18,263,479; 1914-5 £19,272,007; 1915-6 £25,743,149; 1916-7 £27,342,339; 1917-8 £33,285,107; 1918-9 £46,231,430; 1919-20 £60,857,917. This crescendo of revenue gains was the result of two principles working together: the war impetus given to the use of tobacco, including the fact that ladies were in many cases smoking as well as men, and secondly the increased tax. The rate of unstripped tobacco leaf containing 10% or more of moisture, which was 3s. 8d. per lb. in 1914, was raised to 5s. 6d. per lb. from Sept. 22 1915, and this rate lasted till May 1917, other duties such as that on manufactured tobacco being correspondingly increased. On May 3 1917 the duty was increased from 5s. 6d. per lb. to 7s. 4d. but out of deference to the working-classes this increase of 1s. 10d. was reduced on July 15 to an increase of 11d. only, which brought the tax down to 6s. 5d. per lb., at which it remained from July 16 1917 to April 22 1918. The yield kept on the up-grade, notwithstanding the duty, and on April 23 1918 the duty was raised to 8s. 2d. per lb. at which it remained, the 1921 budget having left the main tax unaffected.

There were, however, some specialties in English taxation of distinct note apart from the ordinary tobacco duties. These special features consisted in the application of preferential treatment to empire-grown tobacco and in a surtax on imported cigars. On and after Sept. 1919 the ordinary duties were reduced by one-sixth in the case of tobacco consigned from, and grown, produced or manufactured in, the British Empire. On and after April 1920 an additional duty of 50% *ad valorem* was imposed on imported cigars, reduced by one-third in the case of cigars entitled to preferential rate of duty. This surtax was abolished as from May 10 1921.

War Supplies.—In examining the actual consumption of tobacco one has not merely to consider the imports and revenue figures. There was the large quantity of duty-free cigarettes, cigars and tobacco supplied to H.M. forces, whether in the form of rations or sent out duty free from manufacturers' premises, on orders obtained through tobacconists and from other sources. The dimensions of this most essential portion of the tobacco consumption can be gauged by several indications beyond the broad fact that every soldier or sailor who desired to smoke was well supplied. For instance the British Government chemist in his report for 1916 announced that the samples of tobacco exported on drawback numbered 32,004 or appreciably more than double the highest number examined in any previous year since the introduction of the drawback regulations in 1863. The number of laboratory certificates issued in connexion with samples was 81,889, an increase of no less than 48,179 over the corresponding number for the previous year. This was due to the dispatch of tobacco for the Expeditionary Force. The most direct indication however is afforded by the customs and excise report. This document for 1917-8 records the fact that, apart from ships' stores, the following were in that year the weights of cigarettes, etc., sent to the British Expeditionary forces and on which drawback was granted: tobacco, 123,256 lb.; cigarettes, 7,080,449 lb.; cut, roll, cake or other manufactured tobacco, 5,877,968 lb.; snuff, 525 lb. These figures include the large quantities of cigarettes supplied through tobacconists sending customers' orders to the manufacturers for sending out duty-free tobacco, and also orders sent from firms and other organizations who specialized in soldiers' parcels. They

do not include the considerable number of parcels of cigarettes bought from a tobacconist's duty-paid stock and forwarded in a composite parcel by the soldier's friends. At a Navy and Army Canteen surplus stock sale in Aug. 1920 over 80 million cigarettes and 100 tons of tobacco were disposed of, 60 million of the cigarettes and the tobacco being sold for export only. The cigars for disposal were for the most part replaced into trade channels.

The British Tobacco Control.—The control of food in the United Kingdom, for war purposes, was followed by that of tobacco. The form of control was defined in two orders issued under the Defence of the Realm Regulations. One was called the Tobacco Restriction Order (No. 1) 1917, dated May 24 1917, and made by the Board of Trade under Regulations 2F and 2J, and the other the Tobacco Restriction Order (No. 2) 1917, dated July 11 1917. These two orders between them put the grip of the Board of Trade firmly upon every shred of tobacco which entered the country or was in stock, and controlled its movements, sale and price. The powers given were so full that an immoderate use of them could have paralysed the industry. The fact was that the control was a complete success, alike from the military or munition point of view, from the public point of view, and, greatest feat of all, from the trade point of view. The control lasted from its inception by the Restriction Orders named down to Jan. 11 1919 when the Board of Trade revoked the Orders, stating that "the effect of this revocation is that from the date named all powers exercised by the tobacco control board in regard to the control, importation and distribution and prices of tobacco will be abolished." During the period of control the board had systematized powers in regard to production, manufacture, treatment, use, consumption, transport, storage, distribution, supply, sale or purchase of or dealing in tobacco; they had power to place stocks at the disposal of the Board of Trade; any person delivering tobacco had to keep a record of the quantities delivered; tobacco sold by manufacturers, importers and wholesale dealers was ordered to be as nearly as possible of the same description and was to be sold in similar quantities and under like conditions and to the same customers as in the year 1916. In view of the shortage of shipping and the consequent necessity of economizing the available supplies of tobacco in Britain, an order was made bringing under control the stocks of manufactured and unmanufactured tobacco (of the latter a census was taken) and prohibiting the owners of stocks from dealing with them otherwise than as authorized by the Board of Trade. The order also provided for the regulation of the prices at which tobacco might be sold as from June 1 1917. No restrictions were imposed on the supply of tobacco to H.M. forces overseas. The Control Board at first consisted of the following: Mr. Lancelot Hugh Smith (chairman), Major F. Towle (quartermaster-general's department), and Mr. Gerald Bevan. They were assisted by an advisory committee, representative of all sections of the tobacco trade. The work of the Control Board was arduous; they were called upon to make numerous decisions and the way in which they exercised their powers helped the trade to keep going, guaranteed fair prices to the public and gave general satisfaction. A retail price schedule was issued, and one of these had to be exhibited prominently by every dealer in tobacco. Non-compliance rendered the tobacconist liable to a fine.

The Control Board's issue of Restriction Orders was to conserve supplies, but as time went on, owing to the large requirements of H.M. forces and the continued heavy demand at home, it became evident that the supply to the army might be jeopardized and a rationing system rendered necessary unless additional importations were allowed. The diminution of stocks in the bonded warehouses rendered some step advisable. The Control Board, therefore, though originally formed to restrict, now appeared in a new rôle, that of encouraging supplies, and in Jan. 1918 it was reported that the board were asking that tobacco should, with food and ammunition, be given priority of importation. From March 12 1917 there had been a restriction of clearances. The daily amount of tobacco allowed to be delivered out of warehouse or ship's side was restricted to the daily average quantity for the year ended Dec. 31 1916. But now that more tobacco was needed the question of further imports became urgent. Eventually an arrangement was made by which the British-American Tobacco Co., who had chartered the steamers of the Garland line, should bring in a supply for what became known in control circles and in the trade as "necessitous manufacturers." The result was that all were able to carry on.

Germany and France.—The difficulties of war-time conditions were thus successfully grappled with by the British Control Board. France, under its State *Régie*, did not do so well. It was reported in Dec. 1917 that under the stress of prolonged war the tobacco *régie* had practically broken down. It became well-nigh impossible to buy either tobacco or cigarettes in France. It was stated that owing to the intensification of consumption, due in part to women smoking, the monopoly administration had been taken unawares. Whatever the explanation, the State control did not produce the good results which control of an industry founded on private enterprise brought about in Great Britain. Still France was not so badly off as Germany and Austria. In Oct. 1917 permission was given by the German Government for the manufacture of tobacco-like substances without the employment of tobacco. These substitutes were allowed to be introduced into the trade and were made subject to the tobacco tax.

A schedule of permissible substances was drawn up. What the substances were was made evident to the trade in England by the photographic reproduction in the English trade paper *Tobacco* of advertisements from the *Süddeutsche Tabakzeitung*. One of these advertisements read: "Beech, Chestnut, Lime, Maple, Plane, and Vine leaves in withered and quite dry condition, sound and cleanly sorted in sacks for instant delivery, against banker's security will be purchased. Samples asked for." Another advertiser offered for sale "Cherry leaves, tobacco brown, can be promptly delivered." Meanwhile the proportion of German-grown tobacco in cigars had increased until they were hardly fit to smoke. Large consignments of tobacco acquired by the manufacturers of Bremen, Hamburg, and Dresden from the Balkans were destined for the army, the civil population having to rely upon the substitutes. A similar shortage was experienced in Austria. In both countries drastic control regulations were enforced.

United States.—In accordance with an Act of Congress, approved April 30 1912, the Bureau of the Census collects and publishes (quarterly since 1916) statistics of leaf tobacco held throughout the country. The statistics deal with all manufacturers who during the preceding calendar year produced more than 50,000 lb. of tobacco, 250,000 cigars, or 1,000,000 cigarettes; and dealers who had on an average more than 50,000 lb. of leaf tobacco in stock; included also is the imported leaf tobacco held in bonded warehouses and bonded manufacturing warehouses. No account is taken of smaller establishments or of amounts held by growers.

On Oct. 1 1912 (first official report) there were on hand 1,047,404,560 lb.; on April 1 1921 1,818,781,268 pounds. In every case the April report was the largest, as by that time the gathered crop has been sold. The largest production is "Bright yellow," from Georgia, North Carolina, South Carolina, and Virginia (571,148,382 lb. held April 1 1921); "Burley," from Indiana, Kentucky and Ohio (399,001,600 lb.); and "Dark fired," from Kentucky and Tennessee (178,847,170). Of "Cigar" types the "Pennsylvania" usually ranks first (93,918,626 lb. held April 1 1921); other important types are "New England," "Ohio," and "Wisconsin." A census of the tobacco crop was taken every 10 years after 1839 and of acreage after 1879. The peak of production was reached in 1920 with 1,508,004,000 lb., estimated; the largest producing states were Kentucky (467,500,000 lb., 550,000 ac.), North Carolina (384,120,000 lb., 582,000 ac.), and Virginia (177,300,000 lb., 240,000 ac.). Since 1869 Kentucky has been the leading state. For 1920 the estimated average yield per acre for the United States was 796 lb., as against 894 in 1911, the record year; the variation of production among the states is remarkable, ranging from 600 lb. per ac. in Georgia to 1,510 in Pennsylvania. Of the two recognized classes of tobacco—"Cigar" and "Chewing, Smoking, Snuff and Export"—the former constitutes only one-sixth of the production.

The peak of average prices was reached in 1919. That year the farmers sold 1,440,979,349 lb., ranging from 17 cents in Pennsylvania to 65 cents in Louisiana. The averages for these states in 1911 were 9¢ and 31 cents respectively; in 1920 20 and 40 cents. In the latter year Alabama led with 55 cents.

Although the United States surpasses all other countries in tobacco production, there are large imports of leaf for cigars and cigarettes. In 1920 imports were 82,231,396 lb., of which 18,856,091 lb. came from Asiatic Turkey, chiefly for cigarettes. Cuba furnished 23,616,999 lb., Porto Rico 14,728,645 lb., and the Philippine Is. 1,842,613; the Netherlands 7,720,255 lb. and the Dutch East Indies 2,102,664 pounds. Imported cigars and cheroots come chiefly from the Philippines (over 3,000,000 in 1920). Over five-sixths of tobacco imports enter through the district of New York.

Exports of domestic tobacco and tobacco products from the United States amounted in 1920 to \$288,693,799 as against \$306,861,519 in 1919. Of cigarettes there were exported 15,833,870,000, valued at \$35,977,374; of these over 8,500,000,000 went to China, over 2,000,000,000 to Italy, and over 1,000,000,000 each to British India and the Straits Settlements. Most of the tobacco exports pass through the district of New York.

On Jan. 1 1920 there were in the United States 13,591 tobacco factories, of which 11,483 produced cigars, 1,871 tobacco and snuff, and 237 cigarettes; of bonded manufacturing warehouses there were 13 producing cigars, 2 cigarettes and tobacco, and one tobacco. New York has the greatest number of establishments. The tax on tobacco is an important source of Government revenue. The amount collected rose from \$3,097,620 in 1863 to \$88,063,948 in 1916. Revenue in 1917 was \$103,201,592; in 1918 \$155,757,278; in 1919 \$204,982,560; in 1920 \$294,267,609.

The war period in America has been reviewed in a report of the U.S. War Industries Board. Herein it is stated that men in service used on an average from 60% to 70% more tobacco than they did in civil life. The civil population, due probably to increased prosperity, the cutting down of alcoholic beverages and the sentiment developed by the various campaigns for supplying "smokes" to soldiers, used 15 to 20% more tobacco. No important control beyond some conservation in methods of packing was found necessary, though a price-fixing plan was under consideration when the war was closed. The demand from Europe, it was pointed out, as well as from the U.S. manufacturers, continued to increase, and when producers saw in the autumn of 1917 that they could successfully increase the

price of their manufactured articles, even in face of the increased revenue taxes, very high prices for leaf were assured. It was not until the middle of 1917 that the price of finished products began to rise. The advance was steady and rapid, reaching, 200% of normal on many products by Sept. 1918. The tax on tobacco was increased in Oct. 1917 and Feb. 1919, but these increases formed a relatively small part of the increase in prices.

Leaf Prices.—The unprecedented consumption of tobacco products both in America and Europe reacted on the growers, who planted large crops which they sold under favourable conditions. Prices of the raw material steadily mounted owing to the competition. A really accurate estimate of the effects of war conditions on the price of raw tobacco would detail the various grades and growths and show the alteration as it affected each. The bright cigarette tobaccos of Virginia and the Carolinas were among those which commanded very greatly increased prices, but perhaps the best way of dealing with the question is to take the average prices from 1913 to 1919. The statistical abstract for the United Kingdom gives these average prices in pence per lb. for unmanufactured tobacco as follows: 1913 9.92; 1914 9.75; 1915 8.92; 1916 9.44; 1917 15.47; 1918 21.93; 1919 26.29. Thus it is seen that manufacturers were paying more and more for leaf tobacco, but prices later became more moderate. The cost of eastern leaf from Macedonia and other oriental countries was somewhat high in 1921, but was likely to get lower with increased production.

Waves of Fashion.—Long before 1914 the cigarette had already grown so in public favour that it was rapidly supplanting the pipe and cigar. The war intensified the process. Up to 1914 the most esteemed cigarettes were of the finest Turkish or of bright Virginia tobacco. If anything, the Turkish cigarette was the more used by the fastidious smoker. War conditions caused the cigarette of Turkish or Macedonian tobacco gradually to diminish and the British forces did their arduous work for the most part (and especially after the stocks of the better class Turkish cigarettes had become scarce) on cigarettes of American tobacco. Cigars were of course in request in officers' messes and among certain people at home. Pipes were used by comparatively few. After the Armistice both the cigarette and the cigar, but mostly the latter, seemed to be yielding ground to the pipe. Great Britain has for many years been the home of smoking mixtures in which various kinds of tobacco are blended to make a satisfactory pipe mixture. These mixtures are much appreciated too in America, to which country there is a fair export trade. The British-made briar pipe also sells well in the United States. An influence towards making pipe smoking once more the fashion was the imposition in 1920 by the British chancellor of the exchequer of the *ad valorem* surtax of 50% on imported cigars. This made imported cigars too dear and gave the impression to the public that all cigars were dear. When Mr. Austen Chamberlain subsequently stated, on April 25 1921, in the House of Commons, that "the surtax has lowered the revenue instead of raising it, and has entirely failed to justify itself. Let others learn by the mistake I committed," he might have added that the surtax had temporarily killed the cigar trade.

British Empire Tobacco.—A new prospect was opened in the economic history of tobacco by the institution of the principle of preferential fiscal treatment of tobacco grown, produced, or manufactured in the British Empire. A reduction in the tax of one-sixth is acting as a stimulus to the young tobacco-growing industry of British Africa from Cape Colony to Rhodesia, of Canada and of some other portions of the empire. Growers in the United Kingdom and Ireland have also been encouraged by an allowance. This preferential taxation will probably be found of greater significance to the tobacco manufacturing industry and to the smoker than is even the attainment of the laudable object of helping the tobacco farmers of the empire. A quasi-monopoly such as that possessed by the United States and the Balkans does not economically suit the direct buyer (the manufacturer) or the eventual buyer, the smoker. A widening and multiplication of the sources of supply must have a steadying effect on prices. The lesson of the war was that, quite justifiably under the new conditions, very heavy prices had to be paid for all tobacco, whether from America, Nyasaland or elsewhere. For many years the Imperial Tobacco Co. have been large buyers of African tobacco. Their headquarters in Africa are at Blantyre, where they have encouraged the grower. Tobacco grown in Ireland and also in England has been put on the market with some success. In the British system of taxation a rebate of one-third of the excise duty was allowed on tobacco grown in Ireland for experimental purposes prior to 1909, and on tobacco grown in Great Britain up to 1913 inclusive. From those dates arrangements have been made under which certain grants sanctioned by the Treasury are applied in encouragement of the industry. In 1918 the following quantities were grown: England and Wales, 31,844 lb.; Ireland, 77,978 lb.; total, 109,822 lb.; net receipt of duty, £34,482. In 1919: England and Wales, 78,825 lb.; Ireland, 77,837 lb.; total, 156,662 lb.; net receipt of duty, £60,785. (E. S. C.)

TOGOLAND (see 26.1046).—This German protectorate in W. Africa was conquered by Anglo-French forces in 1914, and German sovereignty was renounced by the Peace Treaty.

For some years preceding 1914 efforts had been made to reconcile the natives to German rule. This process began in the schools, where the children were taught to sing the German national anthem and to wave German flags; the teaching of English formerly common in the mission schools was abandoned. But the emigration of natives to the Gold Coast, which had resulted from the harsh methods of Herr W. Horn (governor 1902-5) and other officials was still marked in 1913, while on the east there was a similar attraction to Dahomey. Herr Horn had been dismissed for misconduct; his successor, Count J. von Zech, was more conciliatory to the natives and gave much attention to the development of railways and trade. In 1912 Germany made a departure in its colonial appointments by sending out as governor a member of one of the reigning families, Duke Adolf Friedrich of Mecklenburg, who was known as leader of an expedition which had crossed Africa. The duke was on leave when the World War broke out. He had, however, seen the linking up of Togoland to Germany by submarine cable (Jan. 1913), the extension of agriculture and an expansion of exports.

Maj. von Döring, the acting governor, had the advantage in the critical days of July 1914 of direct communication with Berlin by a wireless station at Kamina, which had just been erected. He made preparations to invade Dahomey, on the assumption that Great Britain would not enter the war. When this supposition was proved to be wrong Maj. von Döring received instructions from Berlin to propose that Togoland and the adjacent French and British colonies should remain neutral. The offer was made to the local authorities concerned but was rejected, in the case of the British by order of the Colonial secretary in London. The chief concern of Berlin in regard to Togoland was to preserve the use of the Kamina wireless station, through which they could communicate with all the other German colonies in Africa, and when the neutrality offer failed, orders were issued for the defence of Kamina. Von Döring made no attempt to defend the coast region: Senegalese Tirailleurs from Dahomey under Capt. A. Castaing occupied Little Popo (Anecho) on Aug. 6 and Togo on Aug. 8. Meanwhile an officer, Capt. E. B. Barker, had been sent under a flag of truce by the acting governor of the Gold Coast to Lome on Aug. 6 to demand the surrender of Togoland to the British. Twenty-four hours' delay was given; on Capt. Barker's return on the 7th he found that the German troops and Maj. von Döring had retired and that the official left behind had instructions to surrender the colony as far as a line drawn 120 km. N. of Lome. The next day co-operation between the French and British forces was arranged and the chief command given to Capt. F. C. Bryant, senior officer on the spot on the Gold Coast.¹

Capt. (temp. Lt.-Col.) Bryant reached Lome, by sea, with two companies of the Gold Coast Regt., on Aug. 12—a total strength of 57 Europeans and 535 natives with 2,000 carriers. He marched N. along the railway towards Kamina, being joined by Capt. Castaing's French contingent (three Europeans and 155 natives) on Aug. 18. The enemy had blown up the railway bridge over the Chra river and strongly entrenched a position in dense bush N. of the stream. This position was attacked on Aug. 22, but was not carried. The German force consisted of 60 Europeans and 400 native soldiers, and they had three machine-guns which were used to good purpose. The German losses were slight, the Allies' casualties were 73 (including 23 killed) or 17% of the force engaged. During the night the Germans evacuated their position and fell back on Kamina. Maj. von Döring had probably learned that a separate French column from Dahomey was within two days' march of Kamina and that a second British column was also approaching that place from the west. While Col. Bryant was preparing to attack Kamina, the Germans, on the night of Aug. 24-5, blew up the wireless station and on Aug. 26 after vain efforts to obtain terms, von Döring surrendered unconditionally. There were found to be 206 Europeans in Kamina. In the previous fighting five Germans had been killed

and 32 taken prisoner. Thus southern Togoland was in the hands of the Allies; in the northern part Yendi surrendered to a British force of one officer and eight men on Aug. 18, while a French column of 630 rifles under Capt. Bouchet, coming from Upper Senegal, covered 310 m. in 20 days in the height of the rainy season and occupied Sansanne Mango and the rest of Togoland with little opposition. Many of the German native troops deserted to the French. Some 200,000 rounds of soft-nosed bullets issued by the German authorities were captured. The conquest of Togoland—a region the size of Ireland—was notable not only for its rapidity and neatness of execution, but for the fact that the operations were conducted entirely by the local authorities and by the troops on the spot when the war began—in this respect the little campaign was unique. After the conquest the country was divided for administrative purposes into British and French zones, the British occupying the western part, including Lome. The natives settled down rapidly under their new masters.

By decision of the Supreme Council May 7 1919, the mandate to administer Togoland was given to Great Britain and France. An agreement of July 10 1919 divided the country into areas to be administered by Britain and France respectively. This agreement, which left the port and district of Lome to Britain, caused some dissatisfaction in French colonial circles and was amended by a convention of Sept. 30 1920 when in exchange for an enlarged area in the interior Lome and the whole of the seaboard—but 32 m.—went to France. The formal transfer of Lome to France followed in Oct. 1920. In the N. the area acquired by Britain included Yendi and adjoining districts, thus bringing the whole of the Dagomba country under British control. Of the total area of the German colony 13,500 sq. m. came under the British mandate and 20,200 sq. m. under the French mandate. Of the pop., estimated (1920) at 1,250,000, some 850,000 lived in the French area. Europeans, mostly British and French officials and traders, numbered about 500. There was also an energetic colony of Syrian traders.

The railways fell within the French area. They consisted (1921) of a line from Lome N.E. to Atakpame, completed in 1911 and 108 m. long; from Lome along the coast to Anecho (27 m.) and from Lome N.W. to Palime (74 m.). They are all of metre gauge. The principal articles of commerce are products of the oil and coconut palms, cotton, maize, cocoa, live stock, rubber, sisal and other fibres. Of these the most important are palm oil and kernels. There is a considerable transit trade between the Gold Coast and Lome and between Anecho and Dahomey. In 1910 exports were valued at £360,000, and imports at £570,000. In 1913, the last full year of German rule, exports were valued at £455,000 and imports at £530,000. Cotton yarns, textiles, hardware and building material were the chief imports. In 1913 Germany took 60% of the exports and supplied 42% of the imports. After the Allied occupation trade for several years was mainly with neighbouring countries and the United Kingdom. In 1918 the value of exports from Lome reached £434,000, and the value of imports £385,000. In 1919 the figures were: exports £880,000, imports £680,000. After 1914 the cultivation of maize, cotton, sisal and cocoa increased—the cocoa exported in 1919 was worth £140,000, the cotton £120,000.

Togoland was the only German protectorate in Africa which had become self-supporting, revenue rising from £132,000 in 1909 to £169,000 in 1913. The Germans levied a poll tax of 6 marks on the natives; on the Allied occupation direct taxation was abolished. Under the British and French the respective portions of Togoland continued to be self-supporting. The British portion was attached to the Gold Coast Colony, the French portion to Dahomey. Local autonomy was preserved. In Aug. 1920 the French established in their area an administrative council, on which non-officials, including one native, had seats, with a consultative voice in drawing up the budget.

See *Togoland* (1920) a British Foreign Office handbook, with bibliography, and for the 1914 campaign the British White Paper *Correspondence relating to the military operations in Togoland* (Cd. 7872, 1915). See also A. F. Calvert *Togoland* (1918). (F. R. C.)

TOKUGAWA, YOSHINOBU [KEIKI], PRINCE (1837-1913), Japanese statesman, was the last Shogun of the Tokugawa Government (see 26.1047), succeeding the 14th Shogun, Iemochi, in 1866. At that time already a man of matured intellect and high capacities, although his succession had been obtained by the conservatives, he soon displayed an advocacy of liberal progress. He showed great diplomatic tact in the solution of the feuds between the Satsuma and Chosu, and also in opposing the anti-foreign agitation supported by the latter. Realizing after a year's time that the proper government of the country was impossible if continued on the lines of feudalism, which was a bar to all progress and a source of continual internal strife, the Shogun handed in his resignation to the Emperor on Oct. 14 1867. This

¹ It may be noted that the Colonial Office attempted to direct the movement of troops on the Gold Coast from London. Capt. Bryant, however, "did not see fit" to modify his plan of operations.

act of sacrifice was the prelude to the dawn of the enlightened Meiji era at the beginning of 1868. The anti-foreign agitation ceased, the Emperor received and treated as honoured guests the representatives of foreign Powers, and Japan was thrown open to the world. Tokugawa, having renounced his shogunate rights, retired to a strictly private life from which he never emerged. He even renounced the succession to his title for his direct heir in favour of a collateral branch of the family. The Emperor Meiji accepted that renunciation, but he gave him another title of prince to be bequeathed to his own son.

TORONTO (see 27.52), the chief city of Ontario, Canada, is the second city in size in the Dominion. In 1911 its pop. was 376,538; in 1921 the estimated pop. was nearly 600,000. Canada's greatest manufacturing district centres about Toronto. The city contained in 1921 about 1,400 factories employing 85,000 hands and producing goods annually to the value of \$300,000,000. The bank clearings in 1920 amounted to \$5,410,214,802, Montreal being the only Canadian city that surpassed Toronto in this respect. Fourteen of the chartered banks of Canada had their headquarters in Toronto in 1921.

Buildings erected since 1911 include St. Paul's Anglican Church, a fine edifice in the early English Gothic style, seating 3,000 persons, the Timothy Eaton Memorial Church, the greatest architectural ornament of Canadian Methodism, erected by the Eaton family at a cost of nearly \$1,000,000; a 20-storey office building by the Royal Bank of Canada; a similar building by the Canadian Pacific railway, and several buildings for the university of Toronto. For several years preceding 1921 a large new Union station was under construction, and in that year was close to completion.

The Toronto hydro-electric system is one of the largest municipal supply undertakings on the continent of America. The management of the distributing system of the city was vested in 1911 in a board of three commissioners. The history of the enterprise has been one of phenomenal growth. Over 171,000,000 k.w. hours were sold during 1917 with a connected load of over 169,000 H.P.

The total assessed property in the city in 1919 was \$642,816,090, an increase of 900% since 1885. A project was under way in 1921 for the building of a 63 m. boulevard driveway by the municipality. The main boulevard which would be 33 m. long and from 100 to 500 ft. wide would completely encircle the city. Toronto took over its own street railways from a private company in 1921, and has since operated them for the benefit of the municipality. The Toronto Exhibition, the largest annual exhibition held on the continent of North America, drew 1,201,000 visitors in 1919. The construction of the Welland Ship Canal, which was in hand in 1921, was expected to make the port of Toronto accessible to the larger vessels plying on the Upper Lakes. A scheme for the development of the harbour, which had been begun previous to 1917, was well under way in 1921. The project included the reclaiming of Ashbridge's Bay, known now as the Harbour Terminal Industrial District, the improving of the waterfront, the deepening of the harbour, and the construction of permanent breakwaters and concrete piers.

Toronto University has benefited greatly by large gifts from Sir John and Lady Eaton, Sir Edmund Osler and Sir Joseph Flavelle. In connexion with it a School of Engineering Research was founded in 1917 and a Faculty of Music was inaugurated the same year. A department of Social Service was founded, and in war time the university established courses for the training of masseuses that drew students from all over Canada. Hart House, a magnificent building in the Gothic style, was built by the university during the war and housed a number of war activities. It contains quarters for both the students' and Faculty unions, a dining hall, a gymnasium, a theatre and extensive offices for undergraduates' use. Dormitory residences were secured for students in the departments of Political Science and Medicine, and new residences were opened for woman students. An Electrical Engineering building, to cost \$350,000, was under construction in 1921, and a University Press was also being built. The attendance at Toronto University in 1921 was well over 5,000, the highest university attendance in the British Empire.

TORPEDO (see 27.53).—In the World War of 1914-8 the torpedo played a most important part, especially as employed by the German submarines during the "ruthless" submarine campaign, which reached its height in April 1917, when enormous losses were caused by it to British and Allied merchantmen and fishing vessels. The total losses of British merchant ships due to submarines during the period Aug. 1914 to Nov. 1918 amounted to over six and a half million tons, and a very large proportion of this can be ascribed to torpedoes. In addition, British naval losses by torpedo over the same period included:—6 battleships, 5 cruisers, 3 light cruisers, 10 leaders, T.B.D.'s and T.B.'s, 4 submarines and 36 miscellaneous craft. Among these were H.M.S.

"Goliath," a battleship of 12,950 tons, sunk by a Turkish T.B.D. in May 1915 in the Dardanelles. That the torpedo menace largely influenced Adml. Jellicoe's tactics at the Battle of Jutland is plain from his own book (*The Grand Fleet, 1914-1916*). At Jutland the Germans on their side sustained considerable loss or damage from torpedoes; the battleship "Pommern" and the light cruisers "Frauenlob," "Wiesbaden" and "Rostock" were sunk in this way, and 10 other ships were hit, three of which subsequently sank from other causes. The Germans fired between 60 and 70 torpedoes during the action and obtained two hits, one on the "Marlborough" and one on the "Shark", the latter ship was sunk.

FIG. 1.—Aeroplane carrying torpedo.

Apart from their use of the torpedo by larger ships, torpedo-boats and destroyers, the World War saw them also made the weapon of the coastal motor boat (C.M.B.), the development of which in 1916 had been made possible by the installation of the internal combustion engine. The first operation on record carried out by British C.M.B.'s armed with torpedoes was an attack on German T.B.D.'s off Ostend, several destroyers being sunk. These C.M.B.'s operated from Dunkirk. Subsequently C.M.B.'s were extensively used off the Belgian coast, and played a most important part in the blocking operations at Zeebrugge. They were also largely used in the Baltic (notably at Kronstadt) and Caspian Seas, and also at Murmansk.

FIG. 2.—Discharge of torpedo from aeroplane.

A more novel use was the discharge of torpedoes from aeroplanes (see figs. 1 and 2). It is claimed that this was first accomplished in 1911 by an Italian, one Capt. Guidoni, who released a 350-lb. torpedo from an 80-H.P. Farman machine. In the same year the matter was taken up by various British naval experts who realized the possibilities of this form of attack from the air. Notable amongst these was Comm. (later Adml.) Murray Sueter. Adml. Fiske of the U.S. navy was also writing on the subject as early as 1912. By the end of 1913, the first British flight was carried out with a Sopwith seaplane carrying a 14-in torpedo off Calshot, Southampton, and special machines were subsequently ordered by the British Admiralty. During 1914 experiments were proceeded with using "Short" seaplanes, and a

especially light torpedo was designed for aircraft purposes. When the World War broke out, it was realized that means would have to be provided to carry the torpedo planes into proximity to their objectives, and H.M.S. "Engadine" and "Riviera" were fitted out for North Sea operations. Later, in May 1915, H.M.S. "Ben-my-Chree" was sent out to the Dardanelles as an aircraft carrier. She carried two torpedo seaplanes, in addition to reconnaissance aircraft. In 1916-17 the first torpedo planes were produced capable of flying off a ship's deck. About this time British naval authorities became convinced of the value of torpedo aircraft, and a large number were ordered. Delivery commenced in 1918 concurrently with special training of torpedo plane pilots, and in Oct. H.M.S. "Argus" embarked the first completed squadron of torpedo planes. In the first instance, experimental work was concentrated at Felixstowe in 1916, and in 1917 a torpedo seaplane school was established at Scapa Flow, which latter station was closed down after the Armistice. A torpedo seaplane school was also opened at Gosport, and experimental work and training is now carried out from here, pilots being embarked from time to time on board the aircraft carriers attached to the fleet.

In Aug. 1915 an attack was made on a 5,000-ton merchant ship by a short torpedo seaplane from H.M.S. "Ben-my-Chree" in the Dardanelles. A hit was obtained amidships, and spray and flying fragments observed. A few days later three Turkish ships at anchor were attacked, one being hit and subsequently gutted by fire, though the hull was salvaged. In the early part of 1917, the Germans, who had a squadron of torpedo planes at Zeebrugge, made several attacks on British merchant ships in the Downs. Three were sunk and one enemy aircraft shot down.

Construction.—In the British service the 18-in. and 21-in. torpedoes are the only sizes now made; the former are supplied for use in submarines, C.M.B.'s and aircraft, and the latter in capital ships, light cruisers and destroyers.

Constructed of steel plating, except for the air chamber, and of circular cross section, the profile of the torpedo is cigar-shaped, with a blunt-shaped head, a parallel portion and a fine run aft to the tail. Commencing from the forward end, the torpedo is divided into six compartments:—the head, the air vessel, the balance chamber, the engine room, the buoyancy chamber, the tail. These may be described as follows. (1) *The Head*.—There are two types, the War-head containing the explosive and the Collision-head used for practice. The former carries a charge of T.N.T. which is detonated on contact by a device known as the pistol, through the medium of a detonator of fulminate of mercury and a suitable priming charge. The pistol itself consists of a metal body which is screwed into the War-head and carries a striker which has externally projecting arms. On one of these arms, coming into contact with any object, the striker is forced in against the resistance of a shearing pin (which is provided for safety), and the detonator is struck. This in turn detonates the "primer" and the main charge. In the case of the "net cutter," used when attacking ships protected by nets, the action is similar, but the cutter is provided in addition with shearing devices for cutting through the meshes and opening up a hole sufficiently large to enable the torpedo to pass through. Nets are not now carried by modern capital ships of any nation, but the net cutter might be of use against net-defended bases. The Collision-head, used for practice, is a steel shell partially filled with cork to insure buoyancy in case of impact with a target ship. It is brought up to approximately War-head weight by filling it with water before practice running, and is so constructed that, on hitting, the fore part collapses, thereby lessening the blow on the plating of the ship and the shock on the torpedo itself. To facilitate recovery, an indicating light is fitted in a pocket in the Collision-head, consisting of phosphide of calcium in a tin container. On coming in contact with water this chemical has the property of spontaneously bursting into flame, which shows on the surface, thereby indicating the position of the torpedo. (2) *The Air Vessel*.—This consists of a special nickel-steel forging containing the compressed air which provides the motive power of the torpedo. It is closed at either end by special dome-shaped pieces, screwed and sweated into place. To the sides of the vessel are secured the lugs or brackets which take the weight of the torpedo in the case of above-water discharges and the stresses on the torpedo on discharge from submerged tubes. (3) *The Balance Chamber* is rivetted and sweated on to the after end of the air vessel, and forms a watertight compartment which contains the depth-keeping mechanism, the heater apparatus and the supply of fuel (either alcohol or petroleum in some form) in a special flask. In this compartment is also situated the charging valve and the stop valve in the main air pipe, which enables pressure to be isolated when it is necessary to remove the after part of the torpedo for examination of engines, etc. The depth-keeping mechanism, Mr. Whitehead's secret, consists of a

pendulum weight and a hydrostatically operated valve, linked together by rods in such a manner that the weight corrects departures from the horizontal trim of the torpedo, whilst the valve keeps the torpedo at its set depth. Their joint action operates the horizontal rudders of the torpedo through the medium of a small air engine termed the servomotor. (4) *The Engine Room* is the next compartment abaft the balance chamber. It is not watertight, and together with the "buoyancy chamber," to which it is rivetted and sweated, forms what is known as the "afterbody." This portion of the torpedo is secured to the "air vessel—balance chamber" portion by a number of screwed bolts, which allows of the torpedo being easily "parted" for examination of the mechanism in the engine room. This mechanism consists of: (a) the engines, which are of the single-acting four-cylinder Brotherhood type, (b) the steering engine or servomotor; (c) the starting valve and counter gear, (d) the reducing valve, which maintains a constant reduced working pressure at the engines, irrespective of the air-vessel pressure, thus insuring an approximately constant speed throughout the set range, (e) oil bottles for lubricating various working parts. The starting valve is operated by an air-lever which projects through the shell of the torpedo and is thrown aft by a downward projecting bolt in the torpedo tube on discharge. In addition to opening the starting valves, the air-lever in its backward movement presses against a rod which releases the gyroscope. The counter gear, which is mounted on the starting valve casing is a piece of mechanism driven off the engines for stopping the torpedo at a pre-determined range. Off the counter is also driven the ignition gear, whose function is to fire the cordite igniters in the "heater" arrangement at a pre-determined moment, and start the combustion of the air and fuel. In the earlier torpedoes, the counter also operated the "sinking gear." This gear can be set to "float" for practice or "sink" for action and when set for the latter adjustment a small valve is lifted at the end of the run and water is admitted into the buoyancy chamber, thus sinking the torpedo, which might otherwise remain a dangerous floating mine. (5) *The Buoyancy Chamber* provides a large proportion of buoyancy of the torpedo, and consists of a thin sheet-steel shell, strengthened up by internal angle rings, to enable it to withstand external pressure, due either to immersion at great depths or to impulse pressures on discharge. To the foremost bulkhead of this compartment are secured the engines. Two watertight tubes run through it, one centrally carrying the propeller shaft, and the other to one side carrying the rod connecting the servomotor or steering engine, and the horizontal rudders. The sinking valve is on this bulkhead. The remaining fittings in this compartment consist of the gyroscope which is fixed to suitable brackets secured to the shell, and the gyroscope rudder rod, which passes through a watertight gland in the after bulkhead. A watertight removable door is also fitted at the bottom of the chamber to obtain access to the gyroscope. This piece of apparatus consists of a comparatively heavy bronze wheel, delicately mounted in ball bearings in an inner horizontal gymbal. This in turn is mounted in an outer vertical gymbal capable of rotational movement within the framework of the instrument. The wheel is initially spun at a high rate of revolution about its axis in the inner gymbal, due to the release of a strong spiral spring in torsion. This release takes place when the air-lever is thrown aft on discharge, after which the whole system of wheel and gymbals is freed from external constraint. The design is such that all axes of rotation of wheel and gymbals meet in a common point at the centre of gravity of the wheel. Consequently, in theory, if the instrument is in adjustment there are no external forces acting on the wheel or system except friction and windage, and, following the well-known dynamical laws of rotating bodies, the spinning axis tends to maintain its direction in space no matter how the apparatus is moved bodily. Practically, of course, slight errors do creep in, due to minute manufacturing differences, etc., but if the gyroscope is in good condition, the effect of these is barely noticeable until the initial wheel speed has dropped considerably. It will therefore be seen that the axis of the spinning wheel provides a datum line, the direction of which is the direction of the gyro wheel on release, i.e. in the longitudinal axis of the tube and torpedo. Subsequent deviations of the torpedo from the correct line in a horizontal plane, cause relative movement of the spinning axis, and fore and aft line of the torpedo. These relative movements are communicated to a delicate rotary valve through the medium of a small pin mounted on the outer gymbal. This rotary valve controls the air supply to a small steering engine which operates rudders on the vertical fins, so bringing the torpedo back to its original direction. (6) *The Tail* is a non-watertight conical steel shell carrying the horizontal and vertical fins and rudders. The fins are fixed to the tail and the rudders are carried in suitable brackets on their after edges. This portion of the torpedo also contains the gearing which enables the two four-bladed propellers to be driven in opposite directions off the same engine. The provision of two propellers is necessary in order that the torpedo shall remain upright during the run, and these are so shaped that the turning effect of one is balanced by that of the other.

The Director.—The name of "director" is given to the sight by means of which the firing officer is enabled to fire the torpedo at the correct moment. This he does by pressing a key which completes the circuit of the electrical portion of the firing gear at the tube. There are a number of types of sight extant, each of which has been

designed to suit special conditions, chiefly as regards environment, e.g. the director on an above-water tube in a torpedo-boat destroyer, the director in the conning tower of a capital ship, etc. The same underlying principle obtains in every case. Suppose, a torpedo be discharged (see fig. 3) from A so as to hit a ship streaming in the direction BC at C. B is the position of the enemy ship at the moment of firing. Completing the triangle on a convenient scale, clearly

FIG. 3.—Diagram illustrating the principle of the Director Sight (A) on own ship at moment of firing, (B) target ship at moment of firing, (C) position of target when torpedo hits.

AC is to BC as "speed of torpedo" is to "speed of sailing"; and AB is the line of sight, its length and direction representing the velocity and direction of the torpedo relative to the target. Alternatively AC is to BC as the "running range of torpedo to hit" is to the "distance the target moves during time of flight of torpedo," and the length of AB is a measure of the firing range. In addition, if AC is taken to represent the maximum running range of the torpedo, the length AB is a measure of the maximum "possible shot" range under a given set of conditions as regards enemy speed and course. If the range-finder range when the sights come on is greater than that represented by the length AB, the torpedo will not reach its objective. It is obvious that a set of three bars, arranged so as to be capable of sliding and pivoting over each other, provide a torpedo sight which can be graduated so that the possible shot range can be read off direct after the sight is adjusted and torpedo fire withheld if necessary. Earlier types actually took this form, a foresight being fitted at the B end of the bar AB and a backsight at A.

It will be seen that the chances of obtaining hits with torpedoes are almost entirely dependent on the correct estimation of the enemy's course and speed, and the officer handling the instrument has to be a highly skilled specialist in these duties. It will also be seen that the effect of errors in estimation will vary in direct proportion to the number of ships comprising the target, and to the running range to obtain a hit, and are inversely proportional to the speed of the torpedo, for any particular speed of enemy. It is therefore clear that attacks on single ships under way are not likely to be successful unless carried out at short range, and that to insure success against an enemy fleet at long range, it is necessary to fire a large number of torpedoes. A large proportion of these will be wasted, but a torpedo-infested zone will result, which the enemy will find difficult to avoid, unless he is prepared to make large alterations of course, and these will undoubtedly affect the efficiency of his gunfire very seriously. The most obvious way of producing these torpedo-infested zones is to employ large numbers of torpedo-boat destroyers against the enemy, but this must not be considered to be an argument for the abolition of torpedo tubes in big ships, the mere fact that torpedoes are carried by opposing capital ships having a considerable bearing on the tactics employed and the ranges at which the action is fought. (W. M. M. R.)

TOSTI, SIR FRANCESCO PAOLO (1846-1916), composer and teacher of singing, was born at Ortona, Abruzzi, April 9 1846. He began his musical studies at Naples at the age of 14. In 1876

he paid his first visit to England; five years later he was appointed teacher of singing to the Royal family and settled in England. He published many songs, which from the first had a wide success, the most famous being "Goodbye," "Ask Me No More," and "For Ever." He was knighted in 1908. He died at Rome Dec. 2 1916.

TOURNEUX, JEAN MAURICE (1849-1916), French man of letters (see 27 107), died in Paris Jan. 13 1916.

TOWNSEND, MEREDITH WHITE (1831-1911), English journalist, was born at Bures, Suffolk, April 1 1831, and educated at Ipswich grammar school. In 1848 he went out to India, and four years later became editor of the *Friend of India*, acting also for some years as *Times* correspondent. In 1860 he returned to England and purchased the weekly *Spectator* (see 19 562). With R. H. Hutton he was joint-editor until 1898, and he was largely instrumental in making it an established success, writing most of the political articles and the opening paragraphs every week. His two chief publications were *The Great Governing Families of England* (1865), written in conjunction with Langton Sanford, and *Asia and Europe* (1901). He died at Little Bookham, Surrey, Oct. 21 1911.

TOWNSHEND, SIR CHARLES VERE FERRERS (1861-), British general, was born Feb. 21 1861, and joined the Royal Marines in 1881. He served at Suakin in 1884, and in the Nile expedition of the following year. He joined the Indian army in 1892 and was present in the Hunza-Nagar operations of that year. He greatly distinguished himself by his gallant defence of the Chitral fort during its prolonged siege in 1895, for which he was rewarded with the C.B. and a brevet majority. Then, in 1897-8, he served with the Egyptian army in the reconquest of the Sudan and won the D.S.O., shortly after which he was transferred to British Infantry. He served for some months in the field during the S. African War, was promoted colonel in 1904, was for some time on the staff in India, afterwards commanded a district in S. Africa, and was promoted major-general in 1911. He was then for some months in charge of a Territorial division at home, after which he went to India to command a brigade.

In April 1915 he was sent to Mesopotamia to take over command of the 6th (Indian) Division in that theatre of war. Aided by some other troops his division worked its way up the Tigris, driving the Turks out of more than one fortified position, and on Sept. 28 Townshend signally defeated the enemy near Kut-el-Amara and occupied the town, while detachments pursued the enemy halfway to Baghdad; shortly afterwards he was instructed to advance and occupy that city. On the move being made, he encountered the enemy in superior numbers at Ctesiphon, and after severe fighting was obliged to effect a retreat of 120 m. to Kut, and there he and his force were speedily hemmed in. A skilful and resolute defence was made, lasting 143 days till the end of April 1916 but then, supplies being exhausted and all efforts at relief having failed, he was obliged to capitulate. He was rewarded with the K.C.B. for his services. He remained a prisoner of war near Constantinople until Oct. 1918, when he acted as intermediary between the Porte and the Allies in adjusting the Armistice. He retired from the army in 1920, and entered Parliament as member for the Wrekin division of Shropshire.

TOY, CRAWFORD HOWELL (1836-1919), American Hebrew scholar (see 27 114), died in Cambridge, Mass., May 12 1919. In 1913 he published *Introduction to the History of Religions*.

TRACTORS.—The petrol tractor for agricultural and kindred purposes is a development of the steam traction engine, widely used for operating grain threshers and to a small extent for ploughing. Steam ploughs were used toward the end of the 19th century on the large ranches of the north-western section of the United States, in Canada and in Egypt. Their usefulness was limited, however, owing to their great weight, which resulted in the packing of the soil and in rather inefficient operation. When the weight of the petrol engine was greatly reduced by motor-car engineers, about 1900, the idea of substituting that type for the heavy steam plant naturally suggested itself.

The first petrol tractors seem to have been those built by the Huber Mfg Co., of Marion, O., in 1898. These were not successful and only 30 were completed. In 1901 the Hart-Parr Mfg. Co., of Charles City, Ia., engaged in the manufacture of petrol tractors, and, although this company met with many difficulties, it was successful and, after 10 years of continuous manufacture, produced in 1920 5,000 tractors. There are two general types of agricultural tractor, the wheeled and the crawler, or caterpillar, types. The crawler type, in which the weight is spread over a large supporting surface on the ground, can pass over marshy land where the wheeled tractor would be mired, and when used for pulling barrows, seeders and other implements over ploughed ground, does not pack the soil as a wheeled tractor would. Early technical development was chiefly toward large tractors, designed to operate from 6 to 12 plough bottoms, because the only farmers who then took an interest in tractors were the owners of large ranches in western America. The largest producers of petrol tractors in the United States between 1905 and 1913 were manufacturers whose main line was general agricultural machinery and steam traction engines, such as the International Harvester Co., the J. I. Case T. M. Co., and Emerson-Brantingham Co. The large petrol tractors of that period were crude in design and very heavy, their frames were built up of heavy rolled channels, and they had driving wheels of enormous diameter. Their great weight naturally rendered them inefficient, for a large proportion of the engine power was consumed in moving the tractor itself. The oil pull tractor shown in fig. 1 is characteristic of tractors of that period

FIG. 1.

Agricultural Tractors—Tractors are usually rated in terms of the number of 14-in. plough bottoms which they will pull. In 1920, of 100 models on the American market capable of pulling two or more bottoms, 20 were two-plough tractors, 42 three-plough, 17 four-plough and the rest were capable of pulling five or more ploughs. Table 1 shows the production of tractors in the United States each year from 1909 to 1920.

Table 1. Tractor Production in the United States

1909	2,270	1915	21,900
1910	4,500	1916	29,070
1911	7,400	1917	62,742
1912	11,400	1918	132,607
1913	7,450	1919	136,102
1914	10,400	1920	203,300

According to a statement issued by the Ministry of Transport, there were 10,161 agricultural tractors in the United Kingdom in 1921. Of the tractors produced in the United States 14,854 were exported in 1917, 36,351 in 1918, 19,693 in 1919, and 29,143 (valued at \$30,850,000) in 1920. It will be seen from the above table that a slump in tractor production occurred in 1913. It was in 1912 that the business in the large tractors of 6-to 12-plough capacities reached its zenith, and thereafter it declined rapidly. The first popular small tractor, the Bull, was brought out the following year, and in 1914, no fewer than 3,000 tractors of this make were sold. Although smaller, it was still of the same crude design as the larger machines, with exposed gears, plain bearings and similar features. About 1916 a number of engineers with motor-car experience entered the tractor field, and as a result of their efforts tractor design was greatly improved. Before 1920 many farm tractors were designed to use paraffin as fuel, because paraffin was considerably cheaper than petrol, and the conditions of engine operation on a tractor

(constant speed and steady, heavy load) made it comparatively easy to burn paraffin with a moderate degree of success. Petrol, however, proved much more satisfactory in the average engine, and when in 1919 the price of paraffin advanced sharply, tractor users generally turned to petrol. The consumption of petrol in gallons per acre is less, there is less difficulty in cold weather and the oil in the crank case does not lose its lubricating value so quickly. For the sake of economical manufacture many of the earlier small tractors were made with only three wheels, but the buying public did not approve of this feature of construction, and the typical 1920 wheeled tractor had four wheels, two in front steering and two in the rear for driving. The Twin City 12-20 H P. tractor shown

FIG. 2.

in fig. 2 is a good example of the lighter tractors based on motor-car practice. The following is a composite description of a 1920 model three-plough tractor, the features mentioned being those found on the greatest number of models of this capacity; there was a four-cylinder, four-stroke vertical engine at the front, of about 43-in bore by 6-in. stroke, adapted to burn either petrol or paraffin. Ignition was by a high-tension magneto with impulse starter. (The latter device consisted of a spring attachment for magnetos specially developed for use on tractors, which made it unnecessary to "spin" the heavy engines in order to generate a spark in the magneto.) The carburetor was fitted with an air cleaner, which prevented gritty dust from getting into the engine and rapidly wearing out the cylinder barrels. These air cleaners usually acted on the centrifugal principle, but in the lava-ash districts on the Pacific coast it was necessary to employ air washers, owing to the lightness of the dust. Behind the engine there was a friction clutch, and then came the change-speed gear, which gave two forward speeds and one reverse. The higher forward speed was for regular use in ploughing and the lower for emergencies, for ploughing up steep inclines, in heavy soil, etc. Then there was a further reduction by gears to the rear axle. The engine speed was limited by a governor to about 800 revolutions per minute, and as the ploughing speed was about 2½ m.p.h., with 48-in. driving wheels, a reduction of roughly 40 to 1 had to be provided between engine crankshaft and rear axle or rear wheels. In the early tractors the final drive was through exposed bull gears directly on the driving wheels, but the typical 1920 tractor had all its gearing enclosed and protected from dust and mud, which is an important feature in a machine

FIG. 3.

operating in the fields during the wet season as well as when the soil is dry and dusty. The wheelbase of the tractor was 96 in. and its weight about 5,000 pounds. The wheels were built up of rolled rims and flat spokes riveted to the hubs and rims. The driving wheels were provided with angle-iron lugs to increase the traction, and the front wheels with central skid rings to make the steering more positive. The front axle was swivelled to the frame at the middle, to permit the wheels to accommodate themselves to uneven ground. In addition to the pivot joint a spring could be used between the axle and the frame at the front to relieve shocks. These 1920 tractors were provided with a belt pulley for operating threshing

machines, wood saws, silo fillers, etc. It was customary to apply a double horse-power rating, for instance, a three-plough tractor was often rated as a 12-25 H.P. machine. This signified that the tractor could develop 25 H.P. on the belt and 12 H.P. on the drawbar, the difference of 13 H.P. being required for moving the tractor itself over the field. In 1917 the Society of Automotive Engineers standardized tractor belt speed at 2,600 ft. p.m. and the drawbar height at 17 inches. Another class of wheeled tractor, having only two wheels, is exemplified by the Moline Universal illustrated in fig. 3. This is intended for cultivating as well as for ploughing and similar work, and has the necessary clearance to pass over plants 2 ft. or more high. Another feature is that, by means of an extension to the control apparatus, it can be operated from the implement drawn, thus dispensing with the need for an extra man in operating a self-binder, for instance. The crawling tractor had one or two continuous-chain tracks on which it ran and which it carried with it. That portion of the chain track in contact with the ground had transverse projecting bars or depressions which caused it to grip the ground firmly, while the upper side of the lower portion of the chain formed a smooth track on which rolled idler wheels carried on the frame of the tractor. The power from the engine was transmitted through a suitable reduction gear to a pair of toothed wheels which engaged with teeth or rollers on the inner side of the track and, when power was applied by letting in the clutch, the tractor rolled ahead on the track and the track at the same time rolled forward. The power was applied to the two chain wheels through a differential gear, and in order to steer a tractor of this kind, one track was held stationary by means of a brake on the shaft of its chain wheel, while all the power was applied to the other chain wheel. The Cletrac tractor shown in fig. 4 was one of

FIG 4

the smallest tractors of this type. Much of the development work in connexion with crawler tractors was done in California, where the Holt, the Best and the Yuba, all tractors made in large sizes, originated. The Holt, which is called a Caterpillar, became the prototype for the "tanks" which played such an important part in the World War. In 1920 many of these large crawler tractors were used for other than agricultural purposes—for example, in oil-fields, in lumbering and in road-building; and the city of New York that you purchased a large number for use in clearing the streets of snow. The lumbering or logging work done was mainly in swampy districts where previously it had been impossible to work with horses except in winter when the ground was frozen, whereas the crawler tractor made logging in such districts possible the year round. The weight on the track of a crawler tractor of the 1920 type was as low as 5 lb. per sq. in., and such a tractor could go into boggy places where no wheeled vehicle could follow.

In 1919 the Legislature of the state of Nebraska passed a law providing that thereafter no tractor should be sold in that state until the manufacturer had first submitted a sample tractor for trial to the Agricultural Engineering Department of the university of Nebraska and the tractor had satisfactorily met the test required. The manufacturer must also satisfy the state authorities that he is maintaining an adequate supply of repair parts within the state. This legislation was the result of complaints of farmers that manufacturers were overrating their tractors. The result was that, during a period when 66 tractors were tested, the majority of 8 were compelled to increase their rated engine speed, 13 altered their horsepower rating, 14 changed some part and 4 were rejected.

Cost of Tractor Ploughing.—The three chief items in the cost of tractor ploughing are fuel, depreciation and man labour. At the tractor trials held at Lincoln, Nebraska, in the autumn of 1919, the fuel

consumption per ac. averaged almost exactly 4 imp. gal. for ploughing in heavy clay soil, and 3 gal. for ploughing on cliff lands. In the corn belt of the United States, where the soil is comparatively light, it has been customary to reckon on a fuel consumption (either petrol or paraffin) of 2.5 U.S. gal. (2 imp. gal.) per acre. On the other hand, in a bulletin of the U.S. Department of Agriculture on "The Gas Tractor in Eastern Farming," a fuel consumption of 3½ U.S. gal. per ac. is made the basis of cost calculations of the eastern section, and in the tractor trials held at Harrisburg, Pa., in 1919 the average fuel consumption of all tractors using paraffin worked out at 3.28 U.S. gal. (2.62 imp. gal.) per acre. The fuel consumption in tractor ploughing varies both with the character and condition of the soil and with the depth of ploughing. The average depth of ploughing at Lincoln was 5½ inches. The resistance of the soil (drawbar pull) averaged 11.5 lb. per sq. in. for the heavy clay soil and 9 lb. per sq. in. for the cliff land. In the corn belt of the United States the soil resistance generally varies between 5.5 and 7 lb. per sq. in., and this explains the low fuel consumption in ploughing there. The estimate here given of the cost of ploughing one acre is based on the results of an inquiry by the U.S. Department of Agriculture among 400 tractor farmers in the Dakotas concerning their experiences in 1917 and 1918. Only one change is made from the estimate of the department, namely, the assumption of a tractor life of seven instead of nine years, which latter figure is admittedly too high. The answers to the questionnaire yielded the averages shown in Table 2.

Table 2. Average Cost and Performance of Tractor Ploughing in the Dakotas.

	Two-plough Tractors	Three-plough Tractors	Four-plough Tractors
First cost . . .	\$1,050	\$1,460	\$2,000
Full working days per year . . .	45	52	64
Acres ploughed per 10-hr. day . . .	6.3	8.5	10.9

Other factors on which the estimate is based are the following: Cost of petrol, \$2.76 per U.S. gal.; paraffin, \$1.52 per gal.; lubricating oil, \$.50 per gal.; grease \$10 per lb.; repairs, 4% of first cost per year; depreciation on a 7-year basis; man labour at \$4.00 per day; interest at 6% on the average investment (one-half of total investment). Such items as housing, insurance and taxes are neglected.

Table 3. Cost of Tractor Ploughing in the Dakotas 1917-8 (Dollars per acre)

Size of Tractor	Total Cost of Ploughing		Fuel		Oil
	Petrol Tractor	Paraffin Tractor	Petrol	Paraffin	
Two-plough . . .	2.21	1.915	0.69	0.395	0.075
Three-plough . . .	1.975	1.68	0.69	0.395	0.075
Four-plough . . .	1.757	1.462	0.69	0.395	0.075
Other Items					
	Grease	Repairs	Depreciation	Man Labour	Interest
Two-plough . . .	0.02	0.15	0.53	0.635	0.11
Three-plough . . .	0.02	0.13	0.49	0.47	0.10
Four-plough . . .	0.02	0.11	0.409	0.368	0.085

With the data here indicated it is possible to make a close estimate of the cost of tractor ploughing under different conditions, as all the basic costs are given. The average soil resistance in the Dakotas may be assumed to be 8 lb. per sq. inch. In heavier soils the area ploughed per day will be less in substantially the inverse ratio of the soil resistance (provided the latter is not excessive). This is borne out by estimates of the ploughing capacities of the tractors which competed in the Lincoln trials of 1919, made by the judges of the event. Averaging the estimates for heavy clay soil (soil resistance 11.5 lb. per sq. in.), and reckoning on the basis of a 10-hr. instead of an 8-hr. day, the following results are obtained: Two-plough tractor, 4½ ac., three-plough tractor, 5½ ac., four-plough tractor, 6½ ac.

To the American and Canadian farmer the advantage of the tractor is not so much that it reduces the cost of ploughing as compared with horses, as that it enables one man to work a much greater acreage. Approximately one-third of several hundred tractor farmers in Illinois circularized by the U.S. Department of Agriculture had increased their acreage by purchasing tractors. Another great advantage is that the tractor permits work to be done quickly when the weather is favourable. For instance, a southern Illinois farmer estimates that in his neighbourhood the yield of Indian corn is reduced by 1 bus. per acre for every day that planting is delayed after May 8. In 1920 the spring was so wet that he was able to work in the field only the first day and the last day of April, not a day in between; but when the weather turned he was able, owing to his tractors, to get his crop in quickly.

Power farming has proved particularly advantageous in the wheat belt of Kansas. For the best yield the land must be ploughed in Aug., when the temperature is often above 100° F. in the shade and very little work can be accomplished with horses. The tractor works as efficiently at this temperature as in winter. Moreover, the tractor can be used also for threshing, and the old practice of contract threshing has been largely superseded by the plan of four or five farmers owning a small threshing machine cooperatively and helping each other thresh their grain, each using his own tractor as the motive power. A three-plough tractor is generally recommended for a 20x36 in. grain separator. Sometimes it is necessary to get a crop into the ground very quickly, and, with a double shift of operators, tractors can then be operated continuously day and night.

Interest in farm tractors increased greatly in Europe during and following the World War. In 1919 and 1920 tractor trials were held at Lincoln, England, the first under the auspices of the Society of Motor Manufacturers and Traders and the second under that of the Royal Agricultural Society. The French Government in 1920 paid a bonus of 25% on the purchase price of tractors of domestic manufacture and 10% on tractors of foreign manufacture. During the war the British, French and Italian Governments contracted for large numbers of farm tractors in the United States. In 1919 there was an international tractor demonstration and test at Sabyholm, Denmark, in which Danish, Swedish, German, British and American tractors were entered. Several demonstrations were also held in France in the years immediately following the World War. French engineers paid particular attention to tractors for use in vineyards, which must be very narrow. Those for use in orchards, on which a number of American manufacturers specialize, must be very low. A somewhat distinct type is the garden tractor for the cultivation of row crops and general work in market gardening. The Beeman, the first model of this type, was put on the market in 1915, and in 1919 about half a dozen other tractors of this type were brought out. For rubber-tired road tractors, see MOTOR VEHICLES, for artillery tractors, see ARTILLERY.

TRACY, BENJAMIN FRANKLIN (1830-1915), American soldier (see 27 127), died in New York City Aug. 6 1915.

TRADE BOARDS.—An important factor in the regulation of wages in England is now represented by the functioning of the trade boards. The Trade Boards Act of 1909 was passed, as a result of considerable agitation on behalf of workers who were employed under "sweated" conditions, with a view to providing machinery by which their wages might be raised to a more satisfactory level.

This Act applied at once to four trades, namely (1) readymade and wholesale bespoke tailoring and any other branch of tailoring in which the board of trade considered the system of manufacture was generally similar to that prevailing in the wholesale trade, (2) the making of boxes or parts thereof made wholly or partially of cardboard, chip, or similar material, (3) machine-made lace and net finishing and the mending or darning operations of lace curtains and lace finishing; (4) hammered and dolted or tinned chain-making. Provision was further made that the Act should be applied to other trades by Provisional Order if the board of trade was satisfied that the rate of wages prevailing in any branch of those trades was exceptionally low as compared with that in other employments. These Provisional Orders required confirmation by Parliament.

In addition to the trades originally specified four trades were subsequently added under the Provisional Order procedure, making a total of eight. The small number of trades to which the Act of 1909 was applied was due partly to the fact that the procedure by Provisional Order was necessarily a slow and cumbersome process, and partly to the severe limits imposed by the provision that a board could only be established where wages were exceptionally low.

In 1918 an amending Act largely extended the scope of the previous Act. During the World War the whole basis of the payment of wages to women had been altered by the Orders made by the Minister of Munitions under Section 6 of the Munitions Act of 1916; and, for a number of women largely in excess of a million, the provisional rate at the conclusion of the war was in the neighbourhood of 7d. to 8d. per hour. It was recognized that if upon the return of peace the protection offered by the Munitions Acts was suddenly withdrawn a reduction of wages of a very disturbing character might ensue, and that it was desirable that the large number of persons, both men and women,

in the unorganized trades, should have a similar measure of protection to that which had been already offered by the Trade Boards Act to those whom it covered.

The new Act made two amendments of a far-reaching character:—

(a) The minister was empowered to apply it to any specified trade "if he is of opinion that no adequate machinery exists for the effective regulation of wages throughout the trade, and that accordingly, having regard to the rates of wages prevailing in the trade, or any part of the trade, it is expedient that the Act should apply to that trade."

(b) In place of the procedure for application of the Acts by Provisional Order, provision was made for the making of a special Administrative Order, the latter a shorter process than the former, although revision of the minister's proposals by Parliament is still provided for.

Further amendments made by the new Act extended the powers of trade boards with regard to the classes of rates of wages which they could fix, and gave them also the right of requiring Government departments to consider any proposal concerning the conditions in their trade which they might care to make.

The effect of the new Act was to make the Acts applicable to a much larger area of industry and to render legislation no longer a means of protection for sweated trades only. This extension of the scope of the Trade Boards Acts, apart from its desirability, having regard to the special conditions likely to prevail during the reconstruction period, was recommended also by the Committee on the Relations between Employers and Employed, presided over by Mr. J. H. Whitley, M.P. This Committee subsequently recommended that, while joint industrial councils should be established for trades which were sufficiently organized to control their own wage matters, it was equally desirable that trade boards should be established for trades which had not yet reached that degree of organization on both sides which would make possible the complete observance of agreements arrived at between organizations. It was made clear that there was no conflict between the two forms of joint organization, and that each was adapted to and intended for a different degree of organization in the trades concerned. In practice the principle indicated by the Whitley Committee was the guiding principle in the establishment of joint industrial councils and trade boards.

A rapid extension of existing trade boards followed, with the result that, at the end of 1920, 49 additional trade boards for England, Scotland, Wales and Ireland had been set up in the following trades, covering about 3½ million persons:—

Great Britain	
Boot and shoe repairing	Dressmaking and women's light clothing
Brush and broom	Grocery and provisions.
Button making	Hat, cap and millinery.
Coffin furniture and casket making.	Milk distributive.
Corset.	
Cotton waste	Scotland.
Flax and hemp spinning and weaving.	Aerated waters.
Fur.	Dressmaking and women's light clothing
General waste.	Hat, cap and millinery.
Hair, bone and fibre	Milk distributive
Jute spinning and weaving.	Grocery and provisions.
Laundry	
Linen and cotton handkerchief, etc.	Ireland.
Made-up textiles	Aerated waters.
Paper bag	Boot and shoe repairing.
Perambulator and invalid carriage.	Brush and broom.
Pin, hook and eye and snap fastener.	Dressmaking and women's light clothing.
¹ { Retail bespoke tailoring.	Flax and hemp spinning and weaving.
Readymade and wholesale bespoke tailoring.	General waste.
Rope, twine and net.	Hat, cap and millinery.
Stamped or pressed metal wares.	Laundry.
Tobacco.	Linen and cotton handkerchief, etc.
Toy.	Milk distributive.
Wholesale mantle and costume.	¹ { Retail bespoke tailoring
	Readymade and wholesale bespoke tailoring.
	Rope, twine and net.
	Tobacco.
	Wholesale mantle and costume.
England and Wales.	
Aerated waters	

¹ Previously the Readymade Tailoring Trade Board (1909). In 1919 two new boards were constituted.

The Trade Boards Acts provide for the appointment of joint bodies, consisting of an equal number of employers' and workers' representatives, together with a minority, usually three or five, independent members known as appointed members. In trades in which women are employed one of the appointed members is a woman. The members of trade boards are all appointed by the Minister of Labour (originally the president of the Board of Trade), who, in the appointment of the employers' and workers' representatives, is bound to consult the organizations on each side respectively. The appointed members are impartial persons of standing nominated by the minister. The procedure of the boards is regulated by statutory regulations made by the Minister of Labour. Such regulations usually make provisions for a method of voting, and the regular reconstitution of the board, in all cases it is provided that no new appointment shall be made to the board by the minister until the board has had an opportunity of being heard. The boards are provided with secretarial assistance by the Ministry of Labour. They have power to form district committees for such areas as they may consider to be necessary, the members of which, like the members of the boards themselves, are appointed by the Ministry of Labour.

The boards are compelled, unless the Minister of Labour relieves them of the duty, to fix a general minimum time-rate for the workers engaged in the trades concerned. A trade board must also in certain cases fix special minimum piece-rates on the application of an employer. A board has power also, if it so desires, to fix general minimum piece-rates, guaranteed minimum time-rates, overtime-rates, rates for special classes of workers, rates for special areas, rates for special processes, rates for any class of work in any special process or in any special area and piece-work basis time-rates. Rates may be fixed so as to come into operation successively on the expiration of specified periods, or to be valid during a specified period. For the purposes of fixing overtime-rates a trade board may declare what are the normal number of hours in the trade during which ordinary rates of wages are payable, but they have no power to limit the number of hours worked.

In fixing a minimum rate so as to apply to any class of workers in a trade, a board may attach to the fixing of the minimum rate a condition that workers who are members of a class must be holders of a certificate from the trade board, or, if the persons are learners, such conditions as the trade board considers necessary for the instruction of these persons in the trade.

Decisions of trade boards come into obligatory operation by confirming order of the Minister of Labour, and the determinations of trade boards have no force until so confirmed. A board's proposals must be published for two months, during which time employers or workers may lodge objections. On the expiration of the two months the board may proceed to fix the rates. If, in the light of objections, they wish to make substantial alterations, they must issue new proposals. The rates when fixed are sent to the Minister of Labour, who must forthwith take them into consideration and, except in special circumstances, either make an order within a month making the rates obligatory or refer them to the board for reconsideration. By this procedure all those engaged in the trade are fully informed as to the proposals, and are given full opportunity of making observations on them, and, further, Parliament, through the Minister of Labour, can be assured that conditions harmful to the general interests of the community are not made binding by statutory rates. If district committees have been established, a trade board, before proposing rates, is compelled to give the district committee concerned an opportunity of being heard on the subject.

The Minister of Labour may at any time direct a trade board to reconsider rates of wages which may be in operation, although he has no power himself to fix rates of wages.

When rates of wages have been made operative they are enforced by inspectors appointed by the Ministry of Labour, and penalties for offences, such as non-payment of rates of wages, failure to post such rates, or keep records, are punishable by fine or imprisonment.

A trade board has power to exempt employers from the payment of minimum rates of wages in respect of workers who, through age or infirmity, are rendered incapable of earning the minimum time-rate, provided that the cases cannot suitably be met in the opinion of the board by employing the worker on piece-work.

Apart from the fixing of minimum rates of wages, the certification of learners and statutory and wage-fixing duties, the trade boards also act as joint consultative bodies for their trades, and have been so recognized by the Government for the purpose of advising them as to the training of disabled men, the training of apprentices, the settlement of disputes and other important matters.

In Sept. 1921 a Committee of Inquiry into the working of the Trade Boards (which was being severely criticized in various quarters) was appointed by the Ministry of Labour, under the chairmanship of Mr. Account Cave.

(H. W.)

TRADE UNIONS (see 27.140*).—The history of Trade Unionism in the United Kingdom and in the United States, during 1911-21, is dealt with in detail, in separate sections, below, and in the various articles under country headings information regarding foreign countries will be found. The industrial unrest of the years immediately preceding the World War was not by any means confined to Great Britain, and in the chief industrial countries notable developments took place in the growth of trade unionism. Trade unions in such countries as France, Germany, Belgium and Austria, where the movement was of comparatively early growth, received large accessions of membership, and trade unions arose in other countries where any form of labour association had been hitherto unknown. Even before the war, however, there were certain notable exceptions. In Russia and Japan, for example, every form of trade union was illegal, and persons participating in trade union organizations did so at the risk of death or imprisonment. Trade unions, therefore, in those countries, either were secret associations working underground, or masqueraded under the guise of friendly societies or other bodies of a similar character. The war had many diverse effects on the various trade union movements. In the Central European countries the privations of the last two years of the war were reflected in a great falling-off in trade union membership. In Germany this was more than compensated for by the reliance of the Republican governments which followed the Armistice upon the help of the trade unions. This brought to the trade unions a great number of new members, with the result that in 1920 the German trade union movement was actually the largest in the world. In Hungary, on the other hand, the "White" government of the regent Horthy, which succeeded the short-lived Soviet republic of 1919, put down Trade Unionism with the utmost severity, some 70% of the leaders being executed. In the new States created by the Treaty of Versailles, trade unionism was in 1921 generally weak, owing to the existence of strong nationalist movements which absorbed the energies of the population, but in some, such as Czechoslovakia, having a large industrial element, there was a trade union movement of some size. In Russia, on the other hand, the trade unions were an integral part of the Soviet Government, and hence the inducement to the average workman to become a trade unionist was greater than in any other country.

International Trade Union Associations.—The chief international trade union body is the International Federation of Trade Unions, to which most of the chief national trade union bodies are affiliated. Its headquarters are in Amsterdam, and in 1921 it had a membership of just under 24 millions. There was an International Federation of Trade Unions in existence before the World War, to which 19 countries were affiliated, with a membership of about seven and a half millions. The structure of this Federation was extremely loose, its activities included the issue of statistics and reports, the passing of resolutions on social legislation, the promotion of unity within the national movements, and the arrangement of international appeals for funds; but as a whole it was of little importance. For instance, the British Trade Union Congress was not affiliated, Great Britain's representative on the International being the General Federation of Trade Unions. Its centre was at Berlin. During the war this Federation fell to pieces, and a new one, the present Federation was founded in 1919. Twenty-four countries were affiliated in 1921, the most important exception being the American Federation of Labor.

The structure of the International Federation of Trade Unions remains very loose. It endeavours to promote the interests of the affiliated bodies and of trade unionism in countries not affiliated, to prevent international blacklegging, to provide funds for purposes laid down in the rules and to promote combined action on questions of trade union interest. In 1920 the Federation attempted, in pursuit of the last object, to carry out a blockade of the White Government in Hungary by international action, but the blockade was unsuccessful. The Federation makes no attempt to interfere with the policy or organization of its affiliated membership. In contrast, the International Council

* These figures indicate the volume and page number of the previous article.

of Trade and Industrial Unions (the "Red" Trade Union International) was found to act, in its own words, as a "militant international committee for the reorganization of the trade union movement." Its headquarters in 1921 were at Moscow and it was dominated by the ideals and influence of the Russian Communist party. It would only accept as members trade unions or minorities of trade unions which it recognized as revolutionary bodies. Besides these two general groupings, there were in 1921 a number of international federations of workers in different trades, of ever varying membership and importance. A list of these, with their membership, where known, and headquarters, is given in the table on page 744.

A table is also given showing comprehensively the membership of trade unions in different countries after the war. This table does not take into account some minor associations and trade unions which are not for various reasons affiliated to any of the important central bodies. Nor does it include overlapping membership, e.g. in Great Britain the General Federation of Trade Unions, whose members are also affiliated to the Trades Union Congress. In such countries as Brazil, Armenia, Lithuania, Turkey, Ukraine, China, the state of organization is not sufficient to include them. In some countries which have been included the figures of membership given are approximate only. This is naturally the case where trade unionism is subject to severe repression, or where a particular organization, such as the Industrial Workers of the World in the United States, has come under the ban of the executive.

Membership of Trade Unions in Different Countries after the War

	Central Organization	No. of Trade Unions Affiliated	Membership of International Federation July 1921
EUROPE:			
Austria (1919)	Trade Union Commission	928,146	1,000,000
Belgium (1920)	Industrial Branch of Parti Ouvrier Belge	670,000	718,410
Bulgaria (1920)	General Federation of Trade Unions (Social Democratic)	28,000	4,000
Czechoslovakia (1920)	Federation of Czechoslovakia Trade Unions	352,000	740,000
Denmark (1919)	Federation of German Trade Unions	300,000	..
	Federation of Trade Unions	277,392	279,255
Estonia (1919)	Association of Free Trade Unions (Syndicalist)	80,000	..
	Trade Union Congress	30,000	..
Finland (1920)	Trade Union Federation	55,000	..
France (1920)	Confédération Générale du Travail	1,500,000	1,500,000
Germany (1919)	Allgemeiner Deutscher Gewerkschaftsbund	7,338,132	8,000,000

UNITED KINGDOM

The history of British trade unionism in 1911-21 was one of almost continuous and unparalleled expansion. Not only did the percentage of trade unionists in all trades materially increase, and the trades and industries in which trade unionism was previously almost unknown reach a comparatively well-organized condition, but the status of trade unions enormously increased and their programmes and policy were canvassed in quarters where before 1910 they met with no attention.

In numbers alone the growth is sufficiently remarkable. At the end of 1910 the Board of Trade reckoned the total number of trade unionists as 2,435,704; at the end of 1919 the official figure was 8,023,761. At the annual Trades Union Congress of 1910 the number of trade unionists represented was 1,630,853; in 1921, it was 6,389,123. This increase was not, of course, evenly distributed between the several industries, though all received a certain share. It was most remarkable on the railways and in agriculture, among employees of the State, such as postal workers and civil servants, among semi-skilled and unskilled workers and women, in several minor industries, particularly those affected by the Trade Boards Acts, and in the later years among professionals and "salary-earners." Draughtsmen, foremen, architects, professional engineers, actors, law clerks and commercial travellers are only a few of the classes in which trade unionism found a new foothold, while in professions such as teaching and journalism it gained a great deal of ground.

The causes of this great increase are many, some operating generally and some in particular cases only. Undoubtedly a very potent factor in all cases was good trade. Trade unions have always, throughout their history, tended to flourish in times of good trade and to decline in trade depressions, when unemployment makes the weekly contribution a serious drain on their members' pockets, and unemployed benefit uses up the central funds. The years from 1910 to 1914 were years of comparatively good trade, and, after the first shock of war was over, they were followed by such a trade boom as had never been known. With five millions of workers withdrawn to the colours, needing to be clothed and provisioned and supplied with munitions, the demand for the services of those who remained was enormous. There was practically no unemployment during the war, and,

although wages did not begin to rise until many months after the war started, they yet rose much more rapidly than trade union contributions, so that the worker found the burden of contributing to a trade union relatively light. The boom continued long after the Armistice, and it was not until 1920-1921 that the subsequent depression began to be heavily felt.

The factor of good trade would reflect favourably upon trade union membership whether in war or peace; but the war years gave an impetus of another kind to organization on trade union lines. From the Treasury Agreement (March 1915) onwards, the Government recognized the trade unions in essential industries as part of the economic and political structure of the country. They were called in to assist in the production of munitions, to share in the running of Government controls, in such cases as the Cotton and Wool Control Boards, and particularly to coöperate in the selection of men for the army. In many cases the trade unions succeeded in gaining exemption for men engaged upon certain occupations, and at one time certain unions were even empowered to issue Trade Cards to their members, protecting them from military service. They were also of necessity consulted in the "dilution" and "substitution" of labour, and they entered into a very large number of agreements fixing the conditions upon which dilutees should be employed, the wages they were to receive, and the restoration of normal practices at the end of the war.

At the same time the cost of living was rising rapidly, and the trade unions were the bodies concerned with demanding commensurate increases in wages. Thus the average worker found that whether he wished to preserve his standard of life, to retain his exemption from the army, or to secure his job against his return, the best way was to become a member of his trade union; and the Government, which preferred in general to negotiate with representative bodies, whether of workmen or employers, contributed in no small degree to their growth.

Again, certain legislative enactments played a large part in increasing trade union membership. Of these, undoubtedly the most important was the National Insurance Act of 1911, with its subsequent amendments. The Act of 1911 was divided into two parts, Health and Unemployment Insurance, and these parts were subsequently amended by separate Acts. Under the Act dealing with Health Insurance, State benefit payable to insured persons who fell ill is administered by Approved Societies, and a number of trade unions, in order to secure closer contact with the workmen in their industries, decided to form Trade Union Approved Societies for the purpose of administering Health Insurance. Many trade unions thus gained a number of members who joined for health insurance and became full trade unionists, as in most cases they were not allowed to join the Approved Society only.

Unemployment Insurance was originally a much smaller experiment, covered by Part II of the 1911 Act; but it gained considerably in importance when the Government in 1920 compulsorily included under unemployment insurance all the industries of the country in which there was any appreciable amount of unemployment. Under the new Act, trade unions which ordinarily paid unemployed benefit were allowed, subject to certain conditions, to administer the State benefit to their members, an allowance being made to them, under certain conditions, for administration costs, and a considerable number of them availed themselves of these provisions. Some trade unions, particularly those catering for skilled workers, also act as labour exchanges for their trades, notifying vacancies and supplying workers, where they are wanted.

Two further enactments, the Trade Boards Act of 1909 (amended and widened in 1918), and the Corn Production Act of 1917, which set up Agricultural Wages Boards with power to fix binding rates of wages, did much to increase the membership of trade unions, particularly in lowly paid industries. It is a commonplace of trade union organization that very low wages make labour difficult to organize, and the Trade Boards and the Agricultural Wages Boards, by raising the rates of the lowest paid classes, enabled them for the first time to afford trade union

of Trade and Industrial Unions (the "Red" Trade Union International) was found to act, in its own words, as a "militant international committee for the reorganization of the trade union movement." Its headquarters in 1921 were at Moscow and it was dominated by the ideals and influence of the Russian Communist party. It would only accept as members trade unions or minorities of trade unions which it recognized as revolutionary bodies. Besides these two general groupings, there were in 1921 a number of international federations of workers in different trades, of ever varying membership and importance. A list of these, with their membership, where known, and headquarters, is given in the table on page 744.

A table is also given showing comprehensively the membership of trade unions in different countries after the war. This table does not take into account some minor associations and trade unions which are not for various reasons affiliated to any of the important central bodies. Nor does it include overlapping membership, e.g. in Great Britain the General Federation of Trade Unions, whose members are also affiliated to the Trades Union Congress. In such countries as Brazil, Armenia, Lithuania, Turkey, Ukraine, China, the state of organization is not sufficient to include them. In some countries which have been included the figures of membership given are approximate only. This is naturally the case where trade unionism is subject to severe repression, or where a particular organization, such as the Industrial Workers of the World in the United States, has come under the ban of the executive.

Membership of Trade Unions in Different Countries after the War

	Central Organization	No. of Trade Unions Affiliated	Membership of International Federation July 1921

station masters. The most important instance of this is the Government's refusal to permit members of the police forces to belong to the Police and Prison Officers' Union.

All this growth has naturally led trade unions to expand their activities, and in many cases to amend their internal administration. The constitutions of some unions in 1921 dated back 50, 60 and 70 years, and were obviously inadequate to the changed situation, so that many experiments in altering them had come under discussion. One particular point of contention, the "shop branch" versus "residence branch" controversy, is dealt with below. Other difficulties centre mainly round the representation, in a large union, of the interests of different crafts and sexes, the method of electing the governing body, the relative power to be assigned to the governing body, to the officers, and to the members themselves, the amount of local autonomy, financial and otherwise, to be granted, and so on. Different unions adopt different solutions. The executive committee or council, for example, is generally elected by vote of the members, either by districts (as in the Iron and Steel Trades Association), or by departments (as in the National Union of Railwaymen); but it may also be elected by general vote of the whole union. Only two important unions, the Amalgamated Engineering Union, and the United Society of Boilermakers, have adopted the principle of an executive committee in permanent session. In some unions the executive committee is theoretically the final governing body, though in such cases the practice of taking a referendum upon most questions of importance really leaves the decision in the hands of the members, others have a general council or delegate meeting sitting for some time which has power to override the decisions of the executive committee on certain subjects; most, though not all, held at fixed intervals a conference or meeting of representatives to receive the report of the executive committee and to discuss policy. The merits of delegate and other representative conferences and of ballot, secret or otherwise, in ascertaining the will of the membership is one of the problems most frequently canvassed among the trade unions. In some cases the general secretary and other officers are appointed and paid by the executive committee, in others they are elected by vote of the members. It will readily be understood that the latter method gives in effect much more power to the secretary than the former, and the position of a trade union secretary and the extent to which he is able to speak for his union and to conclude binding arrangements on its behalf is another problem claiming much discussion.

Differences of practice also exist with regard to the autonomy of branches and sections of trade unions, and the method of declaring or calling off a strike. Some societies allow great freedom of action to their branches and district committees or councils; others, such as the Iron, Steel and Kindred Trades Association, retain all contributions in the hands of the head office, and only allow money to be spent by branches or districts for purposes specifically approved by the central organization. Between these two extremes there is room for a large variety of different methods. Some unions specifically provide in their constitutions that a ballot of the membership must be taken before a strike is declared. In many other cases this is secured by the general practice; and some unions, such as the Miners' Federation insist further that a two-thirds majority in favour of a strike must be secured. The National Union of Railwaymen, on the other hand, allows a strike to be declared by the executive committee, without prescribing any consultation of the membership. Local strikes may in some cases be declared by the local committee, but in most cases, since the strike pay is centrally administered, the sanction of the central office is necessary for a local strike and the central executive has also power to order the men back to work. All these problems of administration require the services of trained men, and the position and education of the trade union official has begun to receive consideration. The trade unions have been slowly coming to the opinion that the work of a trade union official is specialized and requires special training; salaries have been raised, and classes and

summer-schools for trade union officials and organizers are regularly held. Specialization, however, upon organizing and routine work often tends to remove the trade union official from contact with and understanding of the problems of the members whom he serves, and this difficulty has not yet been satisfactorily solved.

Trade unions have gradually extended their activities in many new directions, of which the principal are politics, education, and the control of industry. The political Labour party in its origin rested upon the support of the trade unions, but in 1909 their political activities appeared to have received a check. This was removed by the passing of the Trade Union Act in 1913, which enabled every trade union, after the prescribed ballot had been taken, to collect contributions for political purposes. By 1921 almost every trade union had its political fund, lists of Labour candidates backed by trade union money appeared, and locally the trade union branches played a regular part in the activities of local Labour parties and supported Labour candidates at local elections. Trade unions also began to show considerable interest in the education of their members. During these years the movement towards adult working-class education experienced a great revival. The Workers' Educational Association a body which in connexion with the universities ran a large number of evening courses and summer-schools for working-class students, was supported by the trade unions, some of which became actual partners in its work. The Central Labour College—now the Labour College—a residential college for students of Marxian economics, founded in 1909 by a secession of students from Ruskin College, and subsequently supported by the National Union of Railwaymen and the South Wales Miners' Federation, extended its activities, and class-centres called Labour colleges, on more or less Marxian lines, were set up in Manchester, Glasgow and elsewhere. Trade unions provided a number of scholarships for their members at the Labour colleges and at Ruskin College, Oxford, and in 1921, when the General Council of the Trades Union Congress was set up, a resolution was carried to provide for the unification of working-class education under it.

Trade union interest, however, has not been confined to education proper. The *Daily Herald*, a newspaper founded during a printers' strike in 1912 by the London Society of Compositors, was supported by Labour and trade union funds, and became an important political force, although it was forced temporarily to become a weekly soon after the outbreak of war. Later, in 1913, the trade unions revived an ancient project of running their own newspapers, and the *Daily Citizen* appeared as the first daily newspaper entirely owned and conducted by the British trade union movement. This paper had a short career, and ceased publication in 1915, mainly owing to war conditions, but the trade unions played a large part in the reissue of the *Daily Herald* as a Labour daily, early in 1919. Besides the daily papers, there are a number of local weeklies and monthlies to which trade unions contribute, and some of them also run papers and printing presses of their own. The Labour Research Department, which in 1916 became a federal body composed of trade unions and other Labour bodies contributing to the endowment of research into the history and problems of the Labour movement, shows the increasing interest of the trade unions in specialized research work.

The inclusion of the phrase "control of industry" (see GUILD SOCIALISM) in the aims of the trade unions has played a considerable part in forming their policy, although it has not been generally translated into fact. In the early years of the century, most trade unions, like the Labour party and the Socialists, were assumed to be in favour of the transference of the important industries of the country to the ownership and control of the State. The experience of workers in State-owned industries, notably in the Post Office, suggested that this was inadequate to fulfil trade union aspirations, and between 1911 and 1921 most of them altered it to a demand for "nationalization of industry, with control by the workers engaged therein, amounting in some cases to a demand for a National Guild

(see NATIONALIZATION). The establishment of a National Guild was part of the official programme of the Union of Post Office Workers (founded in 1920). Perhaps the fullest exposition of the new demand was made by the Miners' Federation in its programme presented to the Coal Commission in 1919, but by the autumn of 1921 it had only been translated into action in the building industry. The unprecedented shortage of houses following the war encouraged the Building Trade Unionists of Manchester to form a Building Guild, which offered to produce houses at cost price for the City Council, themselves controlling and providing the labour, guaranteeing full pay in sickness and had weather to all members of the Guild, and relying upon the credit of the municipality to obtain the necessary materials. The example proved infectious, and after many experiments had been made in different towns, the National Building Guild was formed in 1921, with a number of branches, prepared to undertake work upon the same terms for local authorities or private companies or persons. In every case the Guild was initiated by the local branches of the Building Trade Unions, and none but trade unionists were admitted to membership.

Pre-war Developments—Trade union history from 1910-1921 falls into three well-marked periods: the period of industrial unrest which had already begun by 1910 and which increased in intensity right up to the outbreak of war, the war period, and the revival of activity immediately following the Armistice. The two latter, as has been observed, coincided with great trade union prosperity, which continued unbroken for some months after the Armistice, and gradually came to an end, as the slump in trade became more pronounced, from 1920-1921. It may be said that the miners' strike, in the summer of the latter year, and the subsequent acceptance by the miners of heavy reductions in wages, brought to an end the first post-war period in trade union history (see STRIKES).

The years 1910 to 1914 were years of growing industrial unrest. The chief factor underlying this was the steady rise in prices after the year 1906, which more than offset the slight increase in money wages, and produced a feeling in the workman's mind that his real wages were imperceptibly disappearing. Retail prices in London, which in 1906 stood at 2% above the figure for 1900, had reached, in 1911, 9.4% and in 1914, 16.8% above that figure.

Four of the industrial disputes which occurred during those years were of importance in trade union history—the railway and transport strikes of 1911, the miners' strike of 1912, the Dublin strikes of 1913 and 1914, and the London building lock-out of 1914. The principal interest of the first series of strikes lies in the fact that the railwaymen's unions succeeded in paralysing for some days the greater part of the railway system of the United Kingdom, and thereby brought home to many who had not previously realized it, the potential power of trade unionism. The actual disputes, though partly connected with wage-rates, centred mainly around the question of recognition by the employers of the unions of shipping and railway workers. In the former case the owners agreed after some time to negotiate with the trade union representatives, and a settlement was eventually reached; in the latter, a Royal Commission was set up to investigate the working of the Conciliation Board, established in 1907, which had given rise to many complaints, and the Commission's report was accepted by both sides in conference, although the point of "recognition" of the trade unions was never conceded by the railway companies, and remained in dispute until the end of the war. An important result of these strikes was the consolidation of the railwaymen's trade unions. The existence of several separate unions was felt to be a weakness, and in 1913 three of them united to form the National Union of Railwaymen, which enrolled members rapidly and became by far the largest trade union representing railwaymen.

The coal dispute of 1912 brought to the forefront one of the most important principles of trade unionism, that of the legal minimum wage. In the case of "sweated" industries, this had been recognized in the Trade Boards Act of 1909 but had not yet been applied to comparatively highly-paid workers, although in many industries, minimum rates, established by agreements between both sides, but not enforceable at law, were in existence. These rates varied generally from district to district. The principle of a legal minimum, it should be stated, does not necessarily demand that the minimum should be national in its scope, though many trade unions, especially during the war, demanded national minima, and even a national minimum wage for all workers. The Miners' Federation first claimed that miners working in abnormally unfavourable places should be guaranteed a minimum daily rate, and, when this was refused by the coal-owners, extended their demand to cover all men and boys working in coal-mines, and further put forward a schedule of minimum district rates for the various coal-fields. The strike was terminated by both sides' acceptance of the Miners' Minimum Wage Act. This Act provided that rates should be fixed by joint boards, representative equally of mine-owners and

mine-workers, in each of 22 specified areas. If the two sides of any board failed to agree upon a rate, the rate should be fixed by the chairman. The Miners' Federation thus secured the principle of a minimum, but failed to get their schedule generally adopted. They were very unwilling to accept this position, but the ballot having failed to disclose a two-third majority in favour of continuing the strike, it was declared at an end.

The Dublin dispute raised the question of "recognition" in a more acute form, and also provided many examples of "sympathetic" strike action. The employers in Dublin, as a protest against the aggressive trade union policy of the Irish Transport Workers' Union, discharged its members in their employment, bound themselves not to employ in future members of the union, and in many cases insisted that applicants for work should sign a form undertaking to have no dealings with the union. This action roused a great deal of feeling both in Ireland and Great Britain, sympathetic strikes occurred, and in British ports dockers and railwaymen refused to handle goods loaded in Dublin by non-union labour. The imprisonment of James Larkin on a charge of sedition greatly increased the upheaval. Dublin shipping was practically paralysed by a general strike of dock labourers, and large contributions in money and in kind were sent to the Irish Transport Union by English trade unions and the Cooperative Wholesale Society. The points in dispute were never definitely settled, but the strike petered out gradually in the early months of 1914.

Two important pieces of legislation, the National Insurance Act of 1911 and the Trade Union Act of 1913, were passed during this period.

The War Period.—On the outbreak of war, a general truce between Capital and Labour was immediately arranged. Outstanding disputes, such as the building lock-out, were settled by one side giving way, or by compromise. Trade unions such as the National Union of Railwaymen, which had prepared a national programme of demands, delayed its presentation indefinitely, and the number of industrial disputes dropped from 682 in the first seven months of 1914 to 107 in the last five. For some time trade union history was in abeyance, until the rapid rise in prices and the necessity for increased production, in the munitions trades in particular, turned public attention to it again. The natural concern of most of the unions, as soon as the cost of living began seriously to rise, was with negotiating increases of wages. Other developments of interest took place mainly in two directions, of which the first was the abrogation of trade union conditions and the establishment, over a large number of trades, of compulsory arbitration under the Munitions of War Acts, and the effect of these two upon trade union government, and the second, the tendency, already mentioned, of the Government and the employers' association to admit the trade unions to a quasi-partnership on certain questions—a partnership which endured, as a rule, only as long as rising prices made increased wages both possible and inevitable (see LABOUR SUPPLY).

The necessity for greater production, particularly of munitions and other stores required for the army, early began to be felt, and a series of strikes upon the Clyde brought the question to the fore. The Committee on Production, appointed by the Government in Feb. 1915, reported that one great difficulty in the way of increased production lay in the existence of certain rules and customs of the trade unions. These "trade union conditions" became of considerable importance during the war. Every trade union of any size had before the war certain regulations, some written, but mostly unwritten, under which its members were allowed to work. These regulations related mainly to the class of labour which was permitted to perform any particular job, to the length and character of apprenticeship required, the rates to be paid, and the conditions under which work was to be done. Thus, certain jobs were reserved to fully-skilled craftsmen, had to be paid at the craftsmen's rate, and might only be performed by men who had received a certain training, which in some cases occupied several years. The demand for munitions in large quantities, and the loss of many thousands of skilled men to the army, made it inevitable, in the first place, that semi-skilled and unskilled workmen should be "upgraded" on to skilled work, in order that the necessary increase in the amount of skilled work performed should take place, and secondly, that a great number of new workers should be introduced into the munitions industries, many of whom would only be able to receive a comparatively short training. The Government therefore, in March 1915, invited a number of the leading trade unions in the industries concerned with war production to the famous Treasury Conference, attended by all the unions invited with the exception of the Miners' Federation, at which it was agreed (a) that strikes and lock-outs in the munitions industries should cease for the period of the war, wage disputes being settled under a system of compulsory arbitration; (b) that the trade unions would relax for the period of the war such of their customs as were necessary for the purpose of accelerating war output, it being understood that all such customs should be restored at the end of the war, and that, where labour of a lower degree of skill (such as women's labour) was introduced on work hitherto performed by skilled men, the rate of wages previously paid should not be reduced; (c) that the Government would limit the profits of owners in the munitions industries. The latter clause was made a condition of cooperation by the Amalgamated Society of

TRADE UNIONS

occupied with enrolling new members, negotiating wages, dealing with fresh proposals for the "combing-out" of industrial workers for the army, and in other activities mentioned.

With the Armistice, however, a revival took place, and every union formulated a programme of advance. The programmes varied in individual cases. All included shortening of hours, contention of war advances into permanent wages, and the establishment of national or area minimum rates, and some added national control with workers' control, and full maintenance, by the industry.

State, for workers out of employment. The movement for shorter hours first took shape. During the war, the working hours in industries had been reduced, generally to 48 or 50, and measures made under Government auspices had established the fact that long hours of work did not result in greater production. The Factory Acts, however, and other legal enactments governing the hours of work remained unaltered, and there was a general demand for enactment of a universal 48-hour minimum for all labour. In Jan. 1919, a series of strikes in favour of a 40- or 44-hour week took place in many of the industrial centres. These were suppressed, most immediately the trade unions began to put forward their programmes, of which the most complete was that of the Miners' Federation, which included a national advance of wages, a shorter working week, and a full scheme for the nationalization of the mines under administration under boards composed of representatives of the Miners' Federation and of the Government. On this programme a national mining strike was threatened. There was also unrest on the railways and in the engineering industry, and industrial upheaval was generally predicted. To prevent this, the Government appointed the royal commission on the coal industry (the Sankey Commission) and also called together a large national industrial conference, representative of employers' associations and trade unions, to discuss necessary changes in the laws governing industrial conditions. The Committee elected by the conference (on which the unions in the Triple Industrial Alliance were to serve), after long discussion, agreed upon changes relative to wages, and the relief of unemployment. It had been understood that proposals agreed upon by both sides of the conference be translated into legislation, and upon this basis the discussion had been held; but when the time for legislation came, fresh difficulties were discovered, and the legislation was never introduced.

In 1921 both sides of the conference, finding their efforts fruitless, tendered their resignations. Individual reductions in the hours of labour, however, continued to take place during 1919, but had no legislative force. The Coal Commission sat in session during the time, taking evidence from widely differing sources, and gave a great public sensation by the appearance for the first time of trade union advocates cross-examining the leading owners of coal and mining royalties. An advance of wages and a shorter working week was recommended and became law in the summer. The question of nationalization the Commission was divided; members appointed by the Miners' Federation recommending acceptance of the miners' programme, while the mine-owners' representatives declined to accept it. The chairman's report, recommending nationalization with a measure of workers' control, needing only a part of the miners' demands, was presented to the Government, which after some deliberation declined to accept it. The miners thereupon threatened a strike, and brought it off before the meeting of the Trade Union Congress in London, but failing to obtain adequate promise of support from fellow trade unionists by March, they decided to accept the offer. The Coal Commission was the first instance of a tribunal, representative of employers and trade unions, being set up under Government auspices to pronounce upon a particular dispute, considerable disappointment was expressed in trade union circles at the Government's refusal to carry out its findings. The Government, however, followed in the Industrial Courts Act of 1919, under which the Minister of Labour was empowered to refer any dispute to an industrial tribunal similarly constituted. This Act was used by the trade unions in several instances, notably in the case of disputes at the docks and on the tramways, to obtain redress of their claims. When the trade depression came, however, the Industrial Courts Act was not used. The employers refused to present their demands for wage reductions direct to the unions, and the attempts of the latter to invoke the assistance of the Act were uniformly unsuccessful. During the year the trade unions continued to press forward claims for shorter hours, wage increases, and consolidation of war wages, and in most cases met with some measure of success. The exception was a strike of policemen in London and some other large centres for an increase of wages, which was met by the immediate dismissal of all policemen on the disbandment of the National Union of Police and Prison Guards, and its replacement by a Police Federation under official auspices and prescribed in an Act of Parliament. The disbanded union, however, continued to exist as a rallying ground for the aggrieved policemen. This is the sole occasion in Great Britain in which years when membership in a trade union has been made

by a railway strike of the autumn, which arose out of a wage dispute, was remarkable for the extensive counter-preparations by the Government. The Government, as well as adopting

for the first time the practice of inserting advertisements of its offers and arguments in the public press—a practice which was followed by the National Union of Railwaymen—organized an extensive system of road motor transport, and arranged for the enrolment of volunteers prepared to work on the railways. These preparations were repeated on a more extended scale in the spring of 1921, when a strike of the three unions composing the Triple Alliance was feared, and the Emergency Powers Act of 1920 very considerably strengthened the hands of the executive in dealing with a strike in an "essential industry." The establishment of the principle that the Government was immediately concerned in the case of strikes in "essential industries" to see that necessary services were carried on materially affected the position of the trade unions in those industries. The railway strike ended in a compromise under which the National Union of Railwaymen accepted rates of wages which rose and fell automatically with the rise and fall in the Government figure of the cost of living, a means of adjusting wages which had already been accepted in a number of other trades (see STRIKES).

Early in 1920 the unparalleled shortage of working-class houses led to the remarkable development known as the Building Guild movement. This was the most direct application yet seen of the industrial theories of the Guild Socialists (see GUILD SOCIALISM). A Government committee had previously estimated the shortage of working-class houses at five hundred thousand, but owing to the very high cost of building and materials, the dearth of credit, and the difficulty of recruiting to the building industry the many operatives who had left it in the depression prior to the war, hardly any building was in progress. Under these circumstances, led by Mr. S. C. Hobson, a Manchester Guild Socialist, the building trade unionists of Manchester formed themselves into a Building Guild, and offered to build houses for the Manchester Corporation and other local authorities in Lancashire at cost price plus a percentage to cover office expenditure, incidental charges, and the cost of maintaining every member of the Guild at full wages in sickness, bad weather, or unemployment, thus putting into practice the principle, advocated by many trade unionists, that each industry should be responsible for the full maintenance of all its workers, whether or not there was work available for them at any particular moment. No profits of any kind went to members of the Guild. The credit of the local authority was to suffice for the purchase of plant and materials, many of which were in the first instance bought with the assistance of the Co-operative Wholesale Society. The tenders of the Manchester Guild were accepted in a number of instances, though the limitation placed by the Government on the total number of Guild contracts which could be placed by local authorities considerably restricted their field, and the example of Manchester was followed by over a hundred bodies of trade unionists in various parts of the country, including London, which in the following year united to form a single National Building Guild. The Government's restriction of their work upon public contracts led the Guilds to solicit work from private companies and persons, which in a number of instances was secured. Trade Union Guild Councils, formed for the purpose of inducing other industries to take up the idea, were set up in several districts, and the furnishing trade was among the first to follow suit. The particular interest of the Building Guilds, distinguishing them from other experiments in industrial self-government by the working-classes, lies first in the absence of profits, secondly in the principle of industrial maintenance of all workers, thirdly in its limitation to trade unionists, and fourthly in the co-operation of technical as well as manual workers, representatives of architects and surveyors being given a place on the Guild committees.

With all these various developments trade unions had attained an important place in social life by the end of 1920. But in that year the trade prosperity came to an end. The trades producing for export had been gradually losing practically the whole of their European markets owing to the financial collapse of a great part of Europe, and their workmen were discharged in large numbers. This in its turn reacted upon the home market; there was a sharp fall in wholesale prices, a general and rapid decline in trade, resulting in the total unemployment of between one and two million workpeople in the summer of 1921. As soon as the trade depression became apparent, there was a general move to reduce wages. The legislation confirming war rates of wages for a time had expired during the previous year, and the way was therefore clear for immediate reductions. In many of the minor trades, where trade unionism was weak, there were enforced immediately, the widespread unemployment inclining the workers to accept any reduction rather than run the risk of losing their employment; the well-organized trades were faced during 1921 with demands for wage reductions, of which that presented to the miners was the most important.

Council of Action—One event of this period needs describing in some detail, because it was the most successful attempt of the trade union movement to intervene in foreign politics. The events in Russia, since the revolution of 1917 and the establishment of the Bolshevik Government in Nov. of that year, had been followed with great interest by trade unionists. More from sympathy with anti-capitalist Governments in general than because any but a few of its members were in agreement with Bolshevik theories, the Labour

movement had for long opposed Allied intervention in Russia, and isolated protests, such as that of the dock-workers who refused to load a ship with munitions intended for use against the Bolshevik Government, had been made from time to time. When in the summer of 1920 it appeared that Poland, then at war with Russia, was likely to receive active help from the French and British Governments, the trade union movement rose in protest. The members of the Parliamentary Committee of the Trade Union Congress and the Executive Committee of the Labour party formed themselves into a Council of Action, called a conference of the governing bodies of all the important trade unions, and this conference announced to the Government that a general strike would be called if Great Britain were to enter the Polish war. It was obvious that the general feeling among trade unionists was entirely in agreement with this declaration, and the protest was successful. No active assistance was given to the Polish Government. After the emergency was over, the Council of Action, despite attempts to place it on a permanent basis, gradually ceased to function. During the crisis local Councils of Action, consisting generally of the trade unions affiliated to the local Trade Councils, or Labour party, were formed in most of the large towns. These also gradually lapsed after the crisis was passed (see SYNDICALISM).

Post-war Problems.—The Miners' Federation, during the previous year, after the failure of an attempt to force a reduction in the selling-price of coal—the first important instance of a trade union trying to interfere with the price of its product—had accepted a settlement under which wages varied nationally with the quantity of coal produced. As a result of this settlement, during the following months the quantity of coal produced was considerably above what could be disposed of at a profit. The Government then announced the termination of their control of the coal industry which had been exercised during the war, and of the subsidy which had been previously paid. The mine-owners therefore gave notice of a series of heavy reductions in wages, varying in the different coal-fields and amounting in some cases to 40 and 50%, and when the Miners' Federation refused to accept these reductions, locked the members out. A "sympathetic" strike of the other members of the Triple Industrial Alliance was announced, and the Government made extensive preparations, including the calling up of the army reserve and the enrolment of a national Defence Force under military discipline, for coping with it; but at the last moment the sympathetic strike was cancelled. The Miners' Federation, after a long struggle, was forced to come to terms, and to submit to large reductions in wages, varying from district to district, and thus their object of securing national minimum rates for mine-workers received, for the time at least, a severe setback. The issue of the miners' case seemed to settle the fate of other industries. Few trade unions pursued their resistance to wage reductions to the length of ceasing work, and in fact wages in all industries were considerably lowered during the year. Nor were reductions confined to cases in which the rates were a matter of mutual agreement only; the Agricultural Wages Boards, which fixed the rates for the poorly-paid agricultural industry, were swept away on the repeal of the Corn Production Acts, and an attempt was even made to abolish the Trade Boards.

The result of this was to turn the attention of the trade unions from offensive to defensive action, from advancing wages and shortening hours, to holding as much as they could of what they had already gained, particularly in the matter of shorter hours, and from enrolling thousands of new members to keeping those they already had. It was to be expected that some of these would lapse, and there was a distinct fall in membership, particularly among the unions of unskilled workers and women, towards the end of the year. But the fall was considerably less in proportion than had been experienced in any previous period of bad trade, and in the newer unions of non-manual workers, whose members were less affected by unemployment, it was comparatively slight. There was also, of course, a depletion in the large reserve funds which had been built up during the war, when unemployment benefit and strike benefit were both at their lowest level. The new activities of trade unionism, however, were not curtailed as might have been expected. Trade unions continued to find money to pay the election expenses of Labour candidates, they continued to show interest in research and education, and one of the most important schemes, that for unifying working-class education under the Trade Union Congress, was actually passed during the first year of the depression.

Organization in 1921.—British trade unionism in 1921 presented a picture which at first sight appears exceedingly confused. There were upwards of a thousand trade unions, varying in membership from a score to several hundred thousand, and organized upon all manner of different bases, from the pure craft union to the "all-grades" union enrolling everyone, skilled or unskilled, in any industry; and these unions were united in many different federations and cross-federations. Only two or three hundred of these unions were of national importance, the rest being mainly survivals from an earlier date, or local societies organizing localized industries. Even among the larger unions, however, there were important diversities of scope and structure. The largest single unit, the Miners' Federation, was industrial in its character, embracing most of the workers in or about the mines. The Miners' Federation was also the most important instance of a trade union basing its branch

membership upon the place of work of its members, most other trade unions, except the postal unions, adhering to the "locality" branch. Another large trade union on an industrial basis was the National Union of Railwaymen, though in this case two other bodies of some size, the Railway Clerks' Association and the Associated Society of Locomotive Engineers and Firemen, also organized certain classes of railway employees. Other industries in which industrial unions of this kind existed were the iron and steel trades, the transport trades, other than railways, the distributive trades, the agricultural industry, and the Post Office, though in all these cases there existed rival societies of considerable importance, in some cases claiming a section of the industry, such as in the case of transport, the sailors and firemen of the merchant service, in some cases such as the Workers' Union in agriculture, ready to embrace the whole. On the other hand, the second largest group, the Workers' Union, was an "all-grades" union open to any workman of any trade, and this form of organization was to be seen, in a somewhat less all-embracing form, in the other general labour unions, which were allied with the Workers' Union in the National Federation of General Workers. The third largest group, the Amalgamated Engineering Union, had yet another basis, being formed by a fusion of kindred craft unions in the engineering trades, open to skilled engineers in all industries, and making little claim upon the unskilled workers in the engineering industry proper. The same principle was to be noticed in the chief trade union of woodmakers and in the clerks' trade union. The confusion was, however, less than would at first sight appear, owing to the existence of federation. Thus the transport trade union was united with other trade unions in the transport industry, by means of the Transport Workers' Federation, a printing federation included the various trade unions in the printing industry, the textile federation most of those in the cotton industry, an engineering and shipbuilding federation those in the engineering and shipbuilding trades, whether they catered for skilled or unskilled workers and so on. Certain bitter disputes continued to exist, of which the chief ranged between the National Union of Railwaymen and the engineering and wood-working trade unions over the workers employed in railway shops, but, speaking generally, most of the trade unions concerned with a single class of workers or a single industry, whatever their private disputes, were all represented in the particular federation, and had a means of acting together in case of emergency. This applied for the most part only to the manual workers' unions. The trade unions representing professional, technical and administrative workers were only in a few cases affiliated to the manual workers' federation. They had, however, federations of their own which occasionally entered into cooperation, and individual unions had sometimes close ties with those of the manual workers.

Larger groupings also existed. Of these by far the greatest continued to be the Trade Union Congress, to which all the important trade unions of manual workers and a few of the unions of brain-workers were affiliated. In 1921 an attempt was made to provide out of the Trade Union Congress a more efficient governing machine for the trade union movement by electing its General Council from various industrial groups, instead of, as heretofore, electing it by general ballot vote of the whole Congress. The experience of the Council of Action and of the miners' strike of 1921 had convinced many of the need for a central executive and direction. Trade unions, however, are slow to surrender their individual autonomy, and little but general powers were given to the new General Council at first, though an increase in affiliation fees provided it with additional funds. It was instructed to work in cooperation with the political Labour party in order to arrange for a separation of function between the industrial and political sides of the Labour movement, and for their cooperation in policy. Such separation and cooperation were long overdue. Owing to the much greater age of the Trade Union Congress, it had formed the habit of dealing with political questions long before the Labour party was founded, and continued to do so. It thus happened that the same items, both industrial and political, would appear for discussion both at the Trade Union Congress and at the Conference of the Labour Party, and this led to a great deal of useless overlapping, even apart from cases, such as the miners' demand for nationalization, which might be considered both industrial and political. At the same time the machinery for consultation between the two bodies was very inadequate, and it often happened that they would take opposite lines of policy. The new scheme of cooperation was intended to remedy these defects. An alliance between the trade unions, the Labour party, and the working-class cooperative movement was also frequently proposed, but was never consummated except on specific occasions, though the cooperative societies frequently rendered assistance to members of trade unions in disputes. There were also other general groupings of less importance. The General Federation of Trade Unions, once regarded as a body almost coequal with the Trade Union Congress, had gradually declined in power to the position of a strike insurance society covering about one-sixth of the trade union movement. The Triple Industrial Alliance was founded in 1915 by the Miners' Federation, the National Union of Railwaymen, and the Transport Workers' Federation, avowedly for the purpose of securing united action by those three bodies on industrial questions. At the time of its formation it excited a great deal of interest, and had it ever

succeeded in functioning effectively it would undoubtedly have wielded immense power; but owing principally to lack of co-ordination between its three constituents, it never took effective action upon an important question, and its last failure to act in the miners' strike of 1921 destroyed much of its prestige among the trade unions. Locally the branches of trade unions were united in Trade Councils, which in some cases were separate from and in other cases united with the local Labour party. These Trade Councils, of which there were several hundreds in the United Kingdom, varied greatly in size and importance. In large towns—where the Trade Council could often trace its history as far back as the eighteenth century—it sometimes wielded important industrial and political influence, while in remote places it was little more than a rallying ground for a few trade union branches to discuss matters of common interest. The Trade Councils for the most part, being composed of trade union branches with little money to spare, suffered from a lack of funds, though in times of crisis these could be partly increased by means of local levies. Their functions were not generally defined. This meant in practice that they were limited by opportunity, and might include many types of activity, from the providing of a hall for local meetings or a local Labour weekly paper, to the temporary control of the whole life of a town during a general strike.

Ireland.—Irish trade unionism, in its later stages, needs separate treatment. Originally trade unionism in Ireland was a weak copy of the British model, but in the first decade of the twentieth century, it became imbued with ideas derived from the American Industrial Workers of the World. Under the leadership of James Larkin and of Connolly (executed after the Easter Rebellion of 1916) militant industrial unionism attained to great power. Its strongest exponent was the Irish Transport and General Workers' Union, which was the leader in the Dublin strikes of 1913, and subsequently went through a period of severe repression. It survived, however, and in 1921 was by far the largest constituent element in the Irish Trade Union Congress and Labour Party. The latter body, which adopted political as well as industrial functions in 1912, acts far more as a central executive for its affiliated societies than does the British Trade Union Congress. Affiliated to it are all the important Irish trade unions, with the exception of some located in Ulster, which are kept apart from it by political and religious differences. There are also affiliated a large number of Trade Councils (including the Trade Council of Belfast), which in weakly-organized districts serve as organizing centres, workers being invited to join the Trade Council until a branch of the appropriate trade union can be founded. This is an important respect in which the Irish Trade Councils differ from those of Great Britain. The Irish movement was strongly republican in its political policy, and had close relations with Dail Eireann on the one hand, and with the Irish agricultural cooperative movement on the other. Most of the Irish industries are organized in the Irish Transport and General Workers' Union, though in certain cases British trade unions have a large Irish membership. The most important of these are the railway and postal employees (organized respectively by the National Union of Railwaymen, the Railway Clerks' Association, and the Union of Post Office Workers, though a purely Irish Postal Trade Union also exists), the engineering, shipbuilding and woodworking employees in Belfast and Dublin and some other large towns, and some women workers, mainly in the east and north, who are organized in the National Union of General Workers. There are also separate Ulster unions, principally in the textile industries, but trade unionism in Ulster, especially in Belfast, is liable to be rent asunder from time to time by political and religious upheavals.

Legal Status.—There were few changes during 1911-21 in the laws relating to trade unionism. The most important of these was the Trades Disputes Act of 1913, which partially undid the effect of the Osborne Judgment. It provided that any trade union might take a ballot of its membership on the question of establishing a fund for political purposes. If a majority of the members is in favour of its establishment, contributions for political purposes may be levied, but no member can be forced to contribute to the political fund who does not wish to do so. In cases where there is a composite subscription, covering all purposes of the trade union, any member can reclaim that part of his subscription which would be devoted to political purposes. The political fund must in all cases be separately administered from the general funds. The Trade Union Amalgamation Act, passed in 1917, removed some of the previous legal restrictions on the amalgamation of trade unions by providing that, where a ballot is taken upon the question of amalgamation, it will be sufficient if fifty per cent of the membership votes, and if of those voting a majority of twenty per cent is in favour of it. Despite this Act, a number of amalgamations have failed owing to an insufficient total of votes having been recorded, and various devices have been adopted for getting round the difficulty.

Finance.—The finance of trade unions showed little change during the decade. Most trade unions slightly raised their subscriptions during the war, in about the same proportions, so that the unions of skilled workers have still a far higher subscription and provide on the average a larger number of benefits to their members than the unions of the unskilled. Again, most trade unions built up fairly large reserve funds during the war—which were considerably depleted during 1920-1,—but here again the increase was greater in the case of the skilled unions. All trade unions made large use of the levy, which is one of the most important elements of trade union finance. It is obvious that strike and unemployment funds, particularly strike funds, cannot be put upon an actually sound basis, so that in most trade unions the method is adopted, when a particular fund seems to be in low water, or some special object demands that an immediate sum of money be available, of imposing, generally after a ballot vote, a levy upon the whole membership. Thus, a trade union may levy itself to provide assistance to a particular branch or strike, or to another trade union, or to finance the *Daily Herald*, or for any other of a variety of purposes, and the practice of imposing levies frequently renders the obligation of a member to his trade union very much greater than would appear from the subscription rates laid down in the rule book.

Authorities.—The volume of publications on British trade unionism has increased very rapidly. Official statistics are to be found in the *Labour Gazette*, published by the Ministry of Labour, in the reports of trade unionism issued by the Board of Trade (not since the war), and in the reports of the Chief Registrar of Friendly Societies. Most of the available information will be found collected in the *Labour Year Book*. For the history, organization and theories of trade unions the standard works are *The History of Trade Unionism* (new edition, 1920) and *Industrial Democracy* (new edition, 1920) by Sidney and Beatrice Webb; *Trade Unionism* by C. M. Lloyd (revised edition, 1921), and *An Introduction to Trade Unionism* (1918) by G. D. H. Cole. All these contain full bibliographies. There are also special studies of trade unionism in particular industries. Of these may be mentioned *Trade Unionism on the Railways* (1917) by G. D. H. Cole and R. P. Arnot, *Village Trade Unions* (1920) by Ernest Selley, and *Women in Trade Unions* by Barbara Drake (1920). The standard work on trade union law is *The Legal Position of Trade Unions*, by H. H. Slessor and W. Smith Clark, and a smaller work by H. H. Slessor, *The Law Relat-*

The Progress of British Trade Unionism, 1910-9.

Industry	1910	1911	1912	1913	1914	1915	1916	1917	1918	1919

ing to *Trade Unions* (1921). For Irish trade unionism see *The Irish Labour Movement* by W. P. Ryan (1920).

By far the most important up-to-date source of information, statistical and historical, for other countries is the *Labour International Handbook*. See also G. D. H. Cole, *The World of Labour*. For Germany see *Trade Unionism in Germany* by W. Stephen Sanders (1916). For Russia see A. Losovsky, etc., *Trade Unions in Soviet Russia* (1920). (M. I. C.)

UNITED STATES

From 1898 to 1904 craft unions in the United States grew in importance, and made substantial gains by aggressive action. In 1905 with a slackening of business prosperity came a loss of faith in trade unionism as the one sure solution of the problems of the working class. The American Federation of Labor had organized the skilled trades but the unskilled had been practically neglected. The crafts seemed unable to cope with the trusts and with an open-shop campaign which drew employers together. Attempts were made to capture the American labour movement for a more radical class struggle. In 1905 the Industrial Workers of the World were organized. A movement to organize the building trades into an industrial union was resisted by the American Federation of Labor, but resulted in the establishment in 1908 of the Building Trades Department of the Federation. In 1909 the United Mine Workers announced their championship of the principle of collective ownership of the means of production. In 1911 the machinists followed. From 1903 we find increasing tendency toward concerted movements of the railway crafts. In 1908 the Railway Employees' Department was formed in the American Federation of Labor to include all the railway unions affiliated with the Federation. In 1916 the four railway brotherhoods, not affiliated with the Federation, acted together to demand the eight-hour day. In 1912 the national convention of the Federation voted down the minority report of the Committee on Education in favour of the principle of industrial unionism, 72 for and 264 against; voting strength, 5,929 for and 10,983 against. The two miners' unions voted solidly in favour of the change. Others in favour were the bakers and confectioners, iron, steel and tin workers, printing pressmen, railway carmen and journeymen tailors. In 1912 labour was weak economically but strong politically, due to its support of the Democratic party, then coming into power. Public hearings before the United States Commission on Industrial Relations in 1914 brought industrial conditions into the light of public opinion, for the first time a commission representing the Government not only pronounced the trade union movement harmless to the best interests of the country, but gave its unqualified approval to labour organization as an institution indispensable in a democracy. The return of business prosperity in 1916, coincident with the sudden decrease of immigration, gave labour a new economic advantage. In 1917 the Government asked and won cooperation of organized labour in producing military supplies. Organized labour was given recognition on Government committees, and the policy of boards which represented the Government in its relations with its employees was to recognize trade union standards of working conditions. The leadership of the American Federation of Labor was strengthened by the attitude of the Government, possibly it was weakened by the fact that the War Labor Board dealt with groups of disaffected workers in the local unions rather than with the national officers, and so made for decentralized control in the unions. After the Armistice labour was again on the defensive, and the increasing number of the unemployed were more ready than they had been to listen to the philosophy of the radical, who can always promise a steady job and a pay envelope every week in the Utopian state. The membership in the relatively conservative American Federation of Labor increased nearly threefold between 1910 and 1920. In 1910 there was a paid-up membership of 1,562,112, in 1915 1,946,347, and 1920 4,078,740. If we include also the membership of organizations suspended from the Federation, the total for 1920 was 4,509,213. Outside the Federation are the four brotherhoods of railway employees with a membership of over 400,000, the Amalgamated Clothing Workers, 200,000, the Amalgamated Textile Workers, 40,000;

and other smaller independent organizations. There are five industrial departments in the American Federation of Labor—building trades, metal trades, railway employees, union label trades, and mining. The six largest of the affiliated unions are the United Mine Workers', the Carpenters' and Joiners', the Machinists', Electrical Workers', Railway Carmen, and the Ladies' Garment Workers.

The National Women's Trade Union League of America was founded in 1903 for the purpose of investigating and giving publicity to conditions of women in industry, and to undertake educational work for wage-earning women, to promote labour legislation and improved labour standards, and to aid trade unions in organizing women. The League stands also for the eight-hour day and the 44-hour week, for a living wage, and for equal pay for equal work regardless of sex. The League is indorsed by the American Federation of Labor and the Canadian Trades and Labour Congress and is represented at their conventions by fraternal delegates. It claims 600,000 trade union women, and has also a large membership of men. It publishes *Life and Labor*, and maintains a training school for organizers. Its headquarters are in Chicago.

The decade 1910-20 saw a movement develop to unionize the teachers as a trade group. The first teachers' union was organized in Chicago in 1902, following the failure of the Teachers' Federation to gain consideration from the school board. As the board insisted that it had no money to pay a "living wage," the teachers investigated city finances, and found that many wealthy corporations had been evading taxes due to the city. In the struggle to force the payment of taxes the teachers received aid from organized labour. Then, at the invitation of the Chicago Federation of Labor, the teachers affiliated with that body. In 1916 the Board of Education dismissed those teachers who had been prominent in trade union activity. In order that these teachers might be reappointed, the union withdrew from the city Federation of Labor. In 1914 the teachers of Cleveland voted to affiliate with the American Federation of Labor, but were prevented by the Board of Education. In 1916 teachers' unions in a number of cities united to form the American Federation of Teachers and affiliated with the American Federation of Labor, but forbade recourse to strikes. The official publication is the *American Teacher*. The first trade union of librarians in the United States was formed in New York City, in 1917, to demand salary increases and a regular system of promotions. In 1918 the Boston Library Employees' Union was organized and affiliated with the American Federation of Labor. Union organizers were active without success at the 1919 and 1920 conventions of the American Librarians' Association.

Trade Agreements.—The economic strength of trade unions is crystallized in trade agreements. Such expression of a joint partnership of Capital and Labour to stabilize industry on the basis of an accepted law is typical of the American labour movement. The earliest national agreement in the United States was that of the iron puddlers in 1866. A national agreement of the stove moulders established in 1891, providing for peaceful adjustment of disputes which might arise, continues in force. In 1897 a general strike in the central competitive district of the bituminous coal-mining industry led to an agreement between the operators and the United Mine Workers' Union. In 1902 the president of the union refused to join in a sympathetic strike on behalf of the anthracite strikers because such action would be disloyal to the agreement. For more than 20 years the International Typographical Union had been arbitrating disputes with the publishers of newspapers. At the convention of the National Publishers' Association in 1900, three publishers were chosen as a committee to deal with labour, to represent, however, not the whole convention, but only those employers who had favoured the measure. Contracts between individual employers and the union had been made prior to this time. This committee effected an agreement with the Typographical Union, to be in force from May 1901 to May 1902, which provided for local boards of three persons, one to represent the publisher, one the union, and the third to be chosen by these two. The board was to decide all disputes in its territory, the *status quo* to prevail until an award should be made. If either party should be dissatisfied with the decision, appeal might be taken to a national board, composed of the publishers' labour committee and the president of the Typographical Union. If they failed to agree, an impartial person was called in. A majority decision was then binding on both parties. In 1902 the agreement was renewed for a five-year period, and again in 1907, revised to

succeeded in functioning effectively it would undoubtedly have wielded immense power; but owing principally to lack of co-ordination between its three constituents, it never took effective action upon an important question, and its last failure to act in the miners' strike of 1921 destroyed much of its prestige among the trade unions. Locally the branches of trade unions were united in Trade Councils, which in some cases were separate from and in other cases united with the local Labour party. These Trade Councils, of which there were several hundreds in the United Kingdom, varied greatly in size and importance. In large towns—where the Trade Council could often trace its history as far back as the eighteenth century—it sometimes wielded important industrial and political influence, while in remote places it was little more than a rallying ground for a few trade union branches to discuss matters of common interest. The Trade Councils for the most part, being composed of trade union branches with little money to spare, suffered from a lack of funds, though in times of crisis these could be partly increased by means of local levies. Their functions were not generally defined. This meant in practice that they were limited by opportunity, and might include many types of activity, from the providing of a hall for local meetings or a local Labour weekly paper, to the temporary control of the whole life of a town during a general strike.

Ireland—Irish trade unionism, in its later stages, needs separate treatment. Originally trade unionism in Ireland was a weak copy of the British model, but in the first decade of the twentieth century, it became imbued with ideas derived from the American Industrial Workers of the World. Under the leadership of James Larkin and of Connolly (executed after the Easter Rebellion of 1916) militant industrial unionism attained to great power. Its strongest exponent was the Irish Transport and General Workers' Union, which was the leader in the Dublin strikes of 1913, and subsequently went through a period of severe repression. It survived, however, and in 1921 was by far the largest constituent element in the Irish Trade Union Congress and Labour Party. The latter body, which adopted political as well as industrial functions in 1912, acts far more as a central executive for its affiliated societies than does the British Trade Union Congress. Affiliated to it are all the important Irish trade unions, with the exception of some located in Ulster, which are kept apart from it by political and religious differences. There are also affiliated a large number of Trade Councils (including the Trade Council of Belfast), which in weakly-organized districts serve as organizing centres, workers being invited to join the Trade Council until a branch of the appropriate trade union can be founded. This is an important respect in which the Irish Trade Councils differ from those of Great Britain. The Irish movement was strongly republican in its political policy, and had close relations with Dail Eireann on the one hand, and with the Irish agricultural cooperative movement on the other. Most of the Irish industries are organized in the Irish Transport and General Workers' Union, though in certain cases British trade unions have a large Irish membership. The most important of these are the railway and postal employees (organized respectively by the National Union of Railwaymen, the Railway Clerks' Association, and the Union of Post Office Workers, though a purely Irish Postal Trade Union also exists), the engineering, shipbuilding and woodworking employees in Belfast and Dublin and some other large towns, and some women workers, mainly in the east and north, who are organized in the National Union of General Workers. There are also separate Ulster unions, principally in the textile industries, but trade unionism in Ulster, especially in Belfast, is liable to be rent asunder from time to time by political and religious upheavals.

Legal Status.—There were few changes during 1911–21 in the laws relating to trade unionism. The most important of these was the Trades Disputes Act of 1913, which partially undid the effect of the Osborne Judgment. It provided that any trade union might take a ballot of its membership on the question of establishing a fund for political purposes. If a majority of the members is in favour of its establishment, contributions for political purposes may be levied, but no member can be forced to contribute to the political fund who does not wish to do so. In cases where there is a composite subscription, covering all purposes of the trade union, any member can reclaim that part of his subscription which would be devoted to political purposes. The political fund must in all cases be separately administered from the general funds. The Trade Union Amalgamation Act, passed in 1917, removed some of the previous legal restrictions on the amalgamation of trade unions by providing that, where a ballot is taken upon the question of amalgamation, it will be sufficient if fifty per cent of the membership votes, and if of those voting a majority of twenty per cent is in favour of it. Despite this Act, a number of amalgamations have failed owing to an insufficient total of votes having been recorded, and various devices have been adopted for getting round the difficulty.

Finance.—The finance of trade unions showed little change during the decade. Most trade unions slightly raised their subscriptions during the war, in about the same proportions, so that the unions of skilled workers have still a far higher subscription and provide on the average a larger number of benefits to their members than the unions of the unskilled. Again, most trade unions built up fairly large reserve funds during the war—which were considerably depleted during 1920–1,—but here again the increase was greater in the case of the skilled unions. All trade unions made large use of the levy, which is one of the most important elements of trade union finance. It is obvious that strike and unemployment funds, particularly strike funds, cannot be put upon an actually sound basis, so that in most trade unions the method is adopted, when a particular fund seems to be in low water, or some special object demands that an immediate sum of money be available, of imposing, generally after a ballot vote, a levy upon the whole membership. Thus, a trade union may levy itself to provide assistance to a particular branch or strike, or to another trade union, or to finance the *Daily Herald*, or for any other of a variety of purposes, and the practice of imposing levies frequently renders the obligation of a member to his trade union very much greater than would appear from the subscription rates laid down in the rule book.

Authorities.—The volume of publications on British trade unionism has increased very rapidly. Official statistics are to be found in the *Labour Gazette*, published by the Ministry of Labour, in the reports of trade unionism issued by the Board of Trade (not since the war), and in the reports of the Chief Registrar of Friendly Societies. Most of the available information will be found collected in the *Labour Year Book*. For the history, organization and theories of trade unions the standard works are *The History of Trade Unionism* (new edition, 1920) and *Industrial Democracy* (new edition, 1920) by Sidney and Beatrice Webb; *Trade Unionism* by C. M. Lloyd (revised edition, 1921); and *An Introduction to Trade Unionism* (1918) by G. D. H. Cole. All these contain full bibliographies. There are also special studies of trade unionism in particular industries. Of these may be mentioned *Trade Unionism on the Railways* (1917) by G. D. H. Cole and R. P. Arnot; *Village Trade Unions* (1920) by Ernest Selley; and *Women in Trade Unions* by Barbara Drake (1920). The standard work on trade union law is *The Legal Position of Trade Unions*, by H. H. Slessor and W. Smith Clark, and a smaller work by H. H. Slessor, *The Law Relat-*

The Progress of British Trade Unionism, 1910–9.
